Topics included

1 Overview of the Controller....79
Cisco 9800 Series Wireless Controllers....80
Configuration data model....80
Initial controller setup methods....80
Restrictions for initial controller setup....81
Interactive help....82
Cisco Support Assistant....82
Product analytics....83

Part I: System Configuration....87

2 New Configuration Model....89
New configuration model, tags, and profile....90
Configuration workflow....90
Tags and their associated profiles....92
RF Tags....92
RF Profiles....93
Site Tags....93
Flex profiles....94
AP join profiles....94
Policy Tag....94
WLAN profiles....95
Policy profiles....95
Methods for associating APs with tags....96
Configure a wireless profile policy (GUI)....97
Configure a wireless policy profile (CLI)....98
Configure a flex profile (GUI)....99
Configure a flex profile....100
Configure an AP profile (GUI)....101
Configure an AP profile (CLI)....106
Configure user for AP management (CLI)....108
Set a private configuration key for password encryption....108
Configure an RF profile (GUI)....110
Configure an RF profile (CLI)....110
Configure a site tag (GUI)....112
Configure a site tag for FlexConnect APs (CLI)....112
Configure policy tag (GUI)....113
Configure a policy tag (CLI)....114

Configure wireless RF tag (GUI)....116
Configure wireless RF tag (CLI)....116
Attach a policy tag and site tag to an AP (GUI)....117
Attach policy tag and site tag to an AP (CLI)....118
Enhanced site tag-based load balancing....119
Prerequisites for Enhanced Site Tag-Based Load Balancing....120
Use cases....121
Configure site load (CLI)....121
Verify enhanced site tag-based load balancing configuration....122
Wireless radio profiles....122
Restrictions....123
Configure a wireless radio profile (GUI)....124
Configure a radio profile and beam selection....124
Configure the number of antennas in a wireless radio profile....125
Configure a slot for each radio in the RF tag profile....126
Verify a radio profile....126
AP filters....128
Set tag priority (GUI)....128
Set tag priority 128
Create an AP filter (GUI)....129
Create an AP filter (CLI)....130
Configure filter priority (GUI)....131
Configure filter priority (CLI)....131
Verify AP filter configuration 132
Location configuration....133
Restriction for location configuration....133
Configure a location for an AP (GUI)....133
Configure a location for an AP (CLI)....134
Add an AP to location (GUI)....135
Adding an Access Point to the Location (CLI)....136
SNMP MIB....137
Verify location configuration....137
Verify location statistics....138

3 Wireless Management Interface....139
Wireless management interfaces....140
Best practices and restrictions for WMI....140
Change the WMI interface when RMI is configured....141
WMI Configuration Tasks....141
Migrate VLANs safely for wireless management....141
Sample interface configuration....142
Configure the WMI interface of a controller (CLI)....142
Verify WMI Settings....144

4 Configure Network Address Translation for Wireless Management IP.....147
Network address translation.....148
CAPWAP discovery.....149
Configure wireless management interface with a NAT public IP (CLI).....149
CAPWAP discovery IP response configuration.....150
Verify NAT settings.....152

5 Hardware Features.....155
BIOS Protection on the Controller.....156
BIOS or ROMMON Upgrade with BIOS Protection.....156
Upgrading BIOS.....156
USB disablement.....157
Disable USB (CLI).....157

6 Smart Licensing Using Policy.....159
Smart Licensing Using Policy.....160

7 Management over Wireless.....161
Management over wireless.....162
Restrictions on management over wireless.....162
Configure management of controller over wireless network (GUI).....162
Configure management of controller over wireless network (CLI).....162

8 Boot Integrity Visibility.....165
Boot integrity visibility.....166
Feature history for boot integrity visibility.....166
Verify software image and hardware.....166
Verify platform identity and software integrity.....167

9 SUDI99 Certificate Support.....171
SUDI certificates.....172
Software selection for SUDI trustpoint certificates.....172
SUDI99 certificate and software support.....173
Backward compatibility.....174
Restrictions of SUDI99 certificates.....174
Disable SUDI99 migration (GUI).....174
Disable SUDI99 migration (CLI).....175

10 Link Aggregation Group.....177
Link aggregation group.....178

Link aggregation control protocol....178
Port aggregation protocol....179
PAgP LAG configuration attributes....179
Port channel interface number....179
Flow control....180
LAG configuration in ON mode....180
Multi-LAG....181
Multichassis link aggregation group....181
Prerequisites for Multi-LAG....181
Restrictions for Multi-LAG....181
Supported topologies....181
Configure link aggregation group....183
Configure a port channel interface (GUI)....183
Create a port-channel interface (CLI)....184
Configure LAG in ON mode (CLI)....184
Add an interface to a port channel (LACP) (CLI)....185
Add an interface to a port channel (PAgP) (CLI)....186
Add a VLAN to a port channel (CLI)....187
Remove a port channel group from a physical interface (CLI)....187
Verify the LAG configuration....188

11 Reload Reason History....191
Reload reason history....192
Feature history....192
Request reload reason history using YANG....192
Reload reason history verification....194

Part II: System Upgrade....199

12 Upgrade the Cisco Catalyst 9800 Wireless Controller Software....201
Software upgrade for Cisco Catalyst 9800 Series Wireless Controller....202
Upgrade the controller software using GUI....203
Upgrade the controller software (CLI)....204
Convert from bundle-mode to install-mode....205
Copy a WebAuth tar bundle to the standby controller (GUI)....209

13 In-Service Software Upgrade....211
In-service software upgrade (ISSU)....212
Prerequisites for performing ISSU....212
Guidelines for ISSU....213
Upgrade software using ISSU (CLI)....214
Upgrade software using ISSU (GUI)....215
Upgrade software using ISSU with delayed commit (CLI)....216

Monitor ISSU....217
Troubleshoot ISSU....220

14 Staggered AP Upgrade....221
Access point upgrade configurations....222
Feature history for access point upgrade management enhancements....222
Access point upgrade configuration and behavior....223
Staggered and serial AP upgrade concepts....223
Controller CLI enhancements for AP upgrade management....224
Warning: Extended upgrade durations for serial and one percent batch modes....224
Configure staggered or serial AP upgrades....224
CLI and GUI options for upgrading APs....225
YANG Model Update....225

15 Software Maintenance Upgrade....227
Software maintenance upgrade....228
Install a SMU (GUI)....231
Install SMU (CLI)....232
Roll back an image (GUI)....232
Roll back SMU (CLI)....233
Deactivate SMU (CLI)....233
Configuration examples for SMU....234
AP device package....234
SMU package and AP image changes....235
Install AP device package (GUI)....236
Install AP device package (CLI)....236
Verify APDP on the Controller 237
Per site or per AP model service pack (APSP)....238
Restrictions and workflow....238
Rolling AP upgrade....239
Install AP service package (GUI)....240
Install AP service package (CLI)....241
Add a site to a filter (CLI)....242
Deactivate an image (CLI)....243
Roll back APSP (CLI)....243
Cancel the Upgrade (CLI)....244
Verify the upgrade....244
Verify AP upgrade on the controller....247

16 Efficient Image Upgrade and Out-of-band AP Image Download....249
Efficient image upgrades for FlexConnect APs....250
Restrictions....250
Efficient image upgrade download....250

Enable pre-download in a FlexConnect AP (GUI)....251
Configure an efficient image upgrade for FlexConnect APs....251
Out-of-band AP image download....258
Feature history for out-of-band AP image download....258
Restrictions for Out-of-Band AP image download....259
Download AP image from controller using HTTPS (CLI)....259
Download AP Image from Controller Using HTTPS (GUI)....260
Verify image upgrade....261

17 Predownloading an Image to an Access Point....265
Image pre-downloads to AP....266
Feature history for AP pre-download....266
Restrictions and best practices for pre-downloading an image to an AP....266
Procedures....267
AP image download time enhancement....273
Configure AP Image Download Time Enhancement (GUI)....274
Configure AP Image Download Time Enhancement (CLI)....275
Verify AP image download time enhancement configuration....276

18 N+1 Hitless Rolling AP Upgrade....279
N+1 hitless rolling AP upgrade and version skew....280
How N+1 hitless rolling AP upgrades work....281
Configure hitless upgrade....281
Verify hitless upgrade....283
Site-based rolling AP upgrade in N+1 network....284
Prerequisites for site-based rolling AP upgrade in N+1 networks....284
Restrictions for site-based rolling AP upgrade in N+1 networks....285
Best practices for N+1 redundancy deployments....285
Configure site-based N+1 upgrade (CLI)....285
Client steering enhancements....297
Client deauthentication....297
Best practice for preserving client connectivity during upgrade....297
Deauthenticate clients....297

19 NBAR Dynamic Protocol Pack Upgrade....299
Network-based application recognition protocol pack upgrade....300
Application visibility controls with DPI....300
NBAR limitations....301
Protocol pack upgrades and custom application configuration....301
Upgrade the NBAR2 protocol pack (CLI)....301
Verify the NBAR2 protocol pack....302

20 Wireless Sub-Package for Switch....303

Wireless sub-packages....304
Install wireless packages....304
Remove wireless package....305
Upgrading wireless packages....305
Boot in install mode....306
Install sub-package in a single step (GUI)....306
Install sub-package in a single step....307
Install multi-step sub-package....307
Install the package on a stack....308
Upgrade to new version of wireless package....309
Deactivate wireless package....309
Enable or disable auto-upgrade....310

Part III: Lightweight Access Points....311

21 Global Use Access Points....313
Global use access points....314
Benefits of global use AP....314
AP mode of options....314
Cloud IDs....314
Onboarding process for Wi-Fi 7 APs....315
Fast offline migration....316
Local status page....319
Offline migration....319
Prevent false or accidental migration....319
Cisco regulatory domain....320
Country code and regulatory domain....320
Best practices for Cisco regulatory domain....321
Examples of country code resolution....321
Regulatory activation file....323
E-Label display....326
E-LABEL compliance status....326
E-Label compliance status of AP models....327
Configure AP E-Label compliance status (GUI)....327

22 Countries and Regulations....329
Country codes....330
Prerequisites for configuring country codes....330
Configure country codes (GUI)....330
Configure country codes (CLI)....331
Configuration examples for configuring country codes....333
Regulatory compliance domain....334
Global country-level domains....334

Remove 8 channel restriction on slot 1 of Cisco Catalyst 9166 series APs....334
Configure XOR 5/6GHz radio slot for 6GHz band (CLI)....335
Ensure 6 GHz radio band persistence after CAPWAP reset....336

23 Security....337
Data Datagram Transport Layer Security....338
Configure data DTLS (GUI)....339
Configure data DTLS (CLI)....339
802.1X authentication....340
EAP-FAST protocol....341
EAP-TLS/EAP-PEAP Protocol....341
Access ports with dual port authentication....342
802.1X authentication limitations....342
Topology....343
Configuring 802.1X authentication type and LSC AP authentication type (GUI)....344
Configure 802.1X authentication type and LSC AP authentication type (CLI)....344
Enable 802.1X on the switch port (CLI)....347
Verify 802.1X on the switch port....349
Verify the authentication type....349
Verify access ports dual port authentication....349
Access point client ACL counters....355
Feature history for Access Point Client ACL Counter....356
AP MAC authorization....356
Feature history for AP MAC authorization....357
Create a AAA RADIUS server (GUI)....357
Configure a AAA RADIUS server (CLI)....358
Create a AAA Group configuration (GUI)....359
Configure a AAA Group configuration (CLI)....359
Create a AAA Group Server configuration (GUI)....361
Create a AAA Group Method List configuration (GUI)....361
Configure AP MAC authorization (CLI)....361
Verify MAC authorization details....362

24 AP Joining....365
Failover priority for APs....366
Guidelines to configure AP failover priority....366
Set AP priority (GUI)....366
Set AP priority (CLI)....366
AP Plug-n-Play....367
Provision AP from PnP server....367
Verify AP tag configuration....368
AP fallback to controllers using AP priming profile....368
AP controller selection and onboarding behavior....369
Restrictions for AP fallback to controllers using AP priming profile....369

Configure AP priming profile (CLI)....370
Configure AP priming using filters (CLI)....371
Configure Per-AP priming (CLI)....372
Verify priming filter configuration....372

25 AP Crash File Upload....375
AP crash files....376
Restrictions for AP crash file upload....376
Configure AP crash file upload process (CLI)....376

26 LED States for Access Points....379
LED states for APs....380
Configure the LED State on APs (GUI)....380
Configure LED state for APs (CLI)....381
Configure LED state in the AP profile....381
Verify LED state for APs....382

27 AP Support Bundle....383
AP support bundle....384
Export an AP support bundle (GUI)....384
Export an AP support bundle (CLI)....385
Monitor the status of support bundle export....386

28 Access Point Memory Information....387
Access point memory information....388
Verify AP memory information....388

29 Access Point Tag Persistency....389
AP tag persistency....390
Recommendation: Rejoin APs after enabling tag persistency....390
Requirement: Match tags across controllers....390
Tag persistency for redundancy scenarios....390
Configure access point tag persistency (GUI)....391
Configure AP tag persistency (CLI)....392
Verify AP tag persistency....392

30 AP Power Save....395
Access point power save....396
Tips for AP power save configuration....397
Requirements for AP power save configuration....397
Best practice for AP power save configuration....397
Warnings for AP power save configuration....397

AP power policies....397
Power-save modes....398
PoE profiles....398
Client wakeup threshold....404
Smart energy scenarios....405
How AP power save policies work....406
Configure power policy profile (GUI)....407
Configure a power policy profile (CLI)....407
Configure a calendar profile (GUI)....408
Configure a calendar profile (CLI)....409
Configure a power policy in an access point join profile (GUI)....410
Map a power profile under an AP profile (CLI)....411
Configure client wakeup threshold (CLI)....412
Configure PoE-Out Interface in Power Profile using GUI....412
Configure PoE-out interface in the power profile....413
Configuration example of power profile....414
Verify access point power policy (GUI)....414
Verify the access point power profile....415
Verify radio spatial streams....416
Verify client threshold....417
Verify PoE-out details....417

31 Real-Time Access Points Statistics....419

Access point real-time statistics....420
SNMP traps and intervals for APs....420
Restrictions for AP radio monitoring statistics....421
Configure access point real time statistics (GUI)....421
Configure access point real-time statistics (CLI)....422
Configure the access point radio monitoring statistics (CLI)....424
Monitor access point real-time statistics (GUI)....425
Verify access point real-time statistics....426

32 AP Configuration....429

AP console configurations....430
Configure the AP console (GUI)....430
Configure the AP console (CLI)....430
Verify the AP console status....431
AP audit configuration....432
Restrictions for AP audit configuration....433
Configure AP audit parameters (CLI)....433
Verify AP audit report summary....433
Verify AP audit report detail....434
Radio support for specified slot number....434
Configure 2.4-GHz radio support for the specified slot number (CLI)....434

Configure 5-GHz radio support for the specified slot number (CLI)....436
Configure 6-GHz radio support for the specified slot number....439
XOR radio support....441
Dual-band radios in Cisco AP models....441
Limitations....442
Configure default XOR radio support (CLI)....442
Configure XOR radio support for the specified slot number (GUI)....445
Configure XOR radio support for the specified slot number (CLI)....446
Verify XOR radio support....449
Receiver only dual-band radio support....449
Enable CleanAir with receiver Only dual-band radio on a Cisco AP (GUI)....449
Enabling CleanAir with receiver only dual-band radio on a Cisco AP (CLI)....449
Disable receiver only dual-band radio on a Cisco AP (GUI)....450
Disable receiver only dual-band radio on a Cisco AP (CLI)....450
Configure client steering (CLI)....451
Verify Cisco APs with dual-band radios....452
OFDMA support for 802.11ax APs....452
Supported modes on 802.11ax APs....453
Configure 802.11AX (GUI)....453
Configure channel width (CLI)....454
Configure 802.11ax radio parameters (GUI)....454
Configure 802.11ax radio parameters (CLI)....455
Set up the 802.11ax radio parameters (CLI)....456
Configure OFDMA on a WLAN (CLI)....456
UNII-3 channels in the -E domain....458
Configure UNII-3 channels for -E domain (CLI)....458
Restrictions and supported APs....459
Verify UNII-3 channel configurations....459
Verify channel width....460
Verify client details....461
Verify radio configuration....462
Cisco flexible antenna port....465
Configure a Cisco flexible antenna port (GUI)....466
Configure a Cisco flexible antenna port (CLI)....466
Verify flexible antenna port configuration....466
Environmental sensors in APs....467
Use cases....468
Configure environmental sensors in an AP profile (CLI)....468
Configure environment sensors (CLI)....469
Verify the AP sensor status....470
Accelerometer sensor support....471
CAPWAP LAG support....474
Supported models....475
Restrictions for CAPWAP LAG support....475
Enable CAPWAP LAG support on controller (GUI)....475

Enable CAPWAP LAG support on controller (CLI)....476
Enable and disable CAPWAP LAG globally on controller....476
Enable CAPWAP LAG for an AP profile (GUI)....477
Enable CAPWAP LAG for an AP profile (CLI)....477
Disable CAPWAP LAG for an AP profile (CLI)....478
Disable CAPWAP LAG support on controller....479
Verify CAPWAP LAG support configurations....479
Configure bulk AP provisioning (GUI)....480
Activate tracking for deactivated infrastructure devices (GUI)....480
CAPWAP message aggregation....481
Control and provisioning of wireless APs message aggregation....481
Guidelines of CAPWAP message aggregation....482
Use cases of CAPWAP message aggregation....482
Configure CAPWAP message aggregation (CLI)....482
Verify CAPWAP message aggregation....483

33 Secure Data Wipe....485
Secure data wipe....486
Feature history....486
Restrictions....486
Supported AP models and software versions....486
Verify data wipe....487

34 Wi-Fi 7 Operations....489
Wi-Fi 7 AP....490
Multi-link operation (MLO)....491
Multi-link statistics....492
Configure 802.11be network parameters (CLI)....492
Configure 802.11be network parameters (GUI)....493
Configure A-MPDU window size in RF radio profile (GUI)....494
Configure A-MPDU window size in RF radio profile (CLI)....494
Enable or disable client serving on AP (GUI)....495
Configure 802.11be MCS rates (CLI)....495
Configure 802.11be radio parameter frequencies (GUI)....496
Configure multi BSSID 802.11be parameters (GUI)....496
Configure multi BSSID 802.11be parameters (CLI)....497
Configure 802.11be parameters (GUI)....498
Monitor 5 GHz radio WLAN slot data (GUI)....498
Monitor 802.11be radio parameters (GUI)....498
Verify multi-link statistics....499
Verify 802.11be parameters....503
Verify 320 MHz details (GUI)....504
Verify multi BSSID details....504
Per WLAN Wi-Fi 7 toggle....505

Feature history for per WLAN Wi-Fi 7 toggle....505
Per-WLAN 802.11be configuration....506
Supported security configurations for 802.11be....507
Beacon-Protection status....508
MBSSID....508
Tx-VAP WLAN of MBSSID set for 6 GHz band....509
Create a new 802.11be profile (GUI)....509
Map the 802.11be profile to a WLAN (GUI)....510
Create and map 802.11be profile (CLI)....510
Verify 802.11be profile details....512
Verify 802.11be profile parameters with MLO mapping....512
Verify 802.11be profile mapping to WLAN....512
Verify VAP status for 802.11ax and 802.11be WLAN on 6 GHz band....513
Verify WLAN downgrade from 802.11be to 802.11ax mode....515
Verify AP WLAN information on 6 GHz band with MBSSID slot....519

35 Troubleshooting Lightweight Access Points....521
Support resources for technical issue resolution....522
Support articles....522
Provide feedback on support documents....522
Disclaimer and caution....523

Part IV: Access Points Modes....525

36 Sniffer Mode....527
Sniffer....528
XOR radio roles....528
Essential hardware and software for sniffer setup....529
Restrictions on sniffer....529
Configure an access point as sniffer (GUI)....529
Configure an access point as sniffer (CLI)....530
Enable or disable sniffing on the AP (GUI)....531
Enable or disable sniffing on the AP (CLI)....532
Configure XOR radio role sniffer support on the access point (CLI)....533
Verify sniffer configurations....534
Verify XOR radio role sniffer configuration....534
Examples for sniffer configurations and monitoring....535

37 Monitor Mode....537
Monitor mode....538
Enable monitor mode (GUI)....538
Enable monitor mode (CLI)....539

38 Management Mode Migration in Cisco Catalyst 916X Access Points.....541
Management mode migration for Cisco Catalyst Wireless 916X Series AP.....542
Regulatory domain.....543
Configure management mode migration (GUI).....547
Export APs migrated to Meraki management mode (GUI).....548
Configure the access point management mode (CLI).....549
Verify the management mode migration details.....550

39 Configure the controller for FlexConnect.....551
FlexConnect Authentication.....552
How FlexConnect authentication works.....553
Controller discovery methods.....554
FlexConnect authentication and switching modes.....555
Local authentication in a FlexConnect AP.....556
Local and backup RADIUS server configuration.....556
Restrictions.....557
Guidelines and restrictions for FlexConnect.....558
Configure a site tag (CLI).....559
Configure a policy tag (CLI).....560
Attach policy and site tags to an access point (GUI).....562
Attach policy tag and site tag to an AP (CLI).....563
Link an ACL policy to the defined ACL (GUI).....564
Apply access control lists on FlexConnect.....565
Configure FlexConnect.....566
Configure the switch at a remote site.....566
Configure the controller for FlexConnect.....567
Configure an access point for FlexConnect.....570
Configure an access point for local authentication on a WLAN (GUI).....570
Configure an access point for local authentication on a WLAN (CLI).....570
Connect client devices to WLANs.....571
FlexConnect ethernet fallback.....571
Configure FlexConnect AP local authentication (GUI).....572
Configure FlexConnect access point local authentication.....573
Configure FlexConnect access point local authentication with external RADIUS server.....576
Configuration example: FlexConnect with central and local authentication.....579
NAT-PAT functionalities in FlexConnect.....580
Create a WLAN.....580
Configure a wireless profile policy and NAT-PAT (GUI).....581
Configure a wireless profile policy and NAT-PAT (CLI).....581
Map a WLAN to a policy profile (CLI).....583
Configure a site tag.....583
Attach policy and site tags to an access point (GUI).....584
Attach a policy tag and a site tag to an access point (CLI).....584

Split tunneling for FlexConnect....585
Restriction: split tunneling for FlexConnect....586
Configure Split Tunneling for a WLAN or Remote LAN....586
VLAN-based central switching for FlexConnect....594
Configure VLAN-based central switching (GUI)....594
Configure VLAN-based central switching (CLI)....595
OfficeExtend AP for FlexConnect....596
Configure OfficeExtend AP....596
Disable OfficeExtend AP....597
Best practices for OfficeExtend AP for FlexConnect....598
OEAP personal SSID support....598
Clearing personal SSID from an OfficeExtend access point....601
Example: viewing OfficeExtend configuration....601
Proxy address resolution protocol....602
Enable proxy ARP for FlexConnect access points (GUI)....602
Enable proxy ARP for FlexConnect access points (CLI)....602
Overlapping client IP address in flex deployment....604
Enable overlapping client IP address in flex deployment (GUI)....604
Enable overlapping client IP address in flex deployment....604
Verify overlapping client IP address in flex deployment (GUI)....605
Verify overlapping client IP address in flex deployment....605
FlexConnect high scale mode....607
Enable PMK propagation (CLI)....607
Flex resilient with Flex and bridge modes....608
Configure a flex profile (GUI)....609
Configure a Flex profile (CLI)....609
Configure a site tag (CLI)....611
Configure a mesh profile (CLI)....611
Associate the wireless mesh to an AP profile (CLI)....612
Attach site tag to an access point (CLI)....613
Configure switch interface for APs (CLI)....614
Flex resilient with flex and bridge mode AP configuration verification....615
SuiteB ciphers in FlexConnect mode....616
Configure SuiteB ciphers (GUI)....617
Configure Suite-B ciphers (CLI)....618
Configure GCMP-128, GCMP-256, or CCMP-256 (CLI)....619
Verify SuiteB cipher status....620

40 OEAP Link Test....621
OfficeExtend Access Point link test....622
Configure OEAP link test (CLI)....622
Perform OEAP link test (GUI)....623
Verify OEAP link test....623

41 Cisco OEAP Split Tunneling....625
Cisco OEAP split tunneling....626
Cisco OEAP split tunneling traffic management....626
Prerequisites for Cisco OEAP split tunneling....627
Restrictions for Cisco OEAP split tunneling....627
Use cases for Cisco OEAP split tunneling....628
How Cisco OEAP split tunneling works....628
Create an IP address ACL (CLI)....628
Create a URL ACL (CLI)....629
Add an ACL to a FlexConnect profile (GUI)....630
Enable split tunneling in a policy profile....632
Verify the Cisco OEAP split tunnel configuration....633

42 Access Points Survey Mode....635
AP survey modes....636
Restrictions for access points survey mode....636

43 AP Deployment Mode....637
AP deployment mode....638
Restrictions for AP deployment mode....638
Configure an AP deployment mode (GUI)....638
View deployment status....639
Configure AP deployment mode (CLI)....639
Verify AP deployment mode....640

Part V: Smart Spaces....643

44 Access Point Location....645
AP auto location support....646
Advanced functionalities in Cisco IOS XE 17.12.1....647
Ultra-wideband ranging....647
Global Navigation Satellite System raw data streaming through gRPC....648
Configure AP geolocation derivation using ranging (GUI)....649
Configure AP geolocation derivation using ranging (CLI)....649
Configure the AP Ranging Parameters through the GUI....650
Configure AP ranging parameters (CLI)....650
Configure AP location (CLI)....651
Configure on-demand AP ranging (CLI)....652
Enable fine time measurement (802.11mc) responder (GUI)....653
Configure fine time measurement (802.11mc) responder....654
Configure air pressure reporting (CLI)....655

Configure AP ultra wide band parameters (GUI)....655
Configure access point ultra wide band parameters (CLI)....656
Verify AP geolocation information....657

45 SS IOT: Implement Wi-Fi Coexistence with ESL....661
Wi-Fi-IoT radio coexistence....662
Feature history for Wi-Fi-IoT radio coexistence....662
Best practices for Wi-Fi-IoT coexistence....663
How Wi-Fi-IoT coexistence works with IOx applications....663
Configuration priority for Wi-Fi-IoT coexistence....664
Create an RF profile for Wi-Fi-IoT coexistence (CLI)....664
Configure Wi-Fi-IoT coexistence (CLI)....665
Tag the RF profile to an AP (CLI)....666
Verify Admin state on RF profile....667
Verify coexistence configuration applied to an AP on controller....669
Verify coexistence summary of all the APs....672
Verify coexistence Wi-Fi statistics....673

46 Smart Spaces - AnyLocate capabilities....675
AnyLocate feature set....676
Feature history for Smart Spaces - AnyLocate capabilities....677
Prerequisites for asset tracking....677
Time difference of arrival (TDOA)....678
Automatic reclustering for clock synchronization....679
Prerequisites for wayfinding configurations....679
Impact of AP downtime on location services....679
Enable UWB wayfinding (GUI)....680
Enable UWB wayfinding (CLI)....680
Configure height above the floor (GUI)....681
Configure height above the floor (CLI)....681
Verify AP UWB wayfinding status....682
Verify AP UWB asset-tracking status....683
Verify AP location information....684
Verify the prerequisites for asset tracking....684

Part VI: Radio Resource Management....687

47 Radio Resource Management....689
Radio resource management....690
Radio resource monitors....690
Radio frequency groups....691
Transmit power control....696
Dynamic channel assignment....696

Coverage hole detection and correction....699
Cisco AI enhanced RRM....699
Restrictions....701
How to configure RRM....701
Configure neighbor discovery type (GUI)....701
Configure neighbor discovery type (CLI)....702
Configure RF groups....703
Configure transmit power control....708
Configure 802.11 RRM parameters....711
Configure advanced 802.11 RRM....721
Monitor RRM parameters and RF group status....724
Monitor RRM parameters....724
Verify RF group status....725
Event-Driven Radio Resource Management 726
Configure ED-RRM on the controller (CLI)....726
Rogue detection - rogue channel width....728
Configure rogue channel width (CLI)....728
Configure rogue classification rules (GUI)....730
Verify rogue channel width....733

48 Coverage Hole Detection....735
Coverage hole detection and correction....736
Configure coverage hole detection (GUI)....736
Configure coverage hole detection (CLI)....736
Configure CHD for RF tag profile (GUI)....739
Configuring CHD for RF profile (CLI)....739

49 Optimized Roaming....741
Optimized roaming....742
Restrictions for optimized roaming....742
Configure optimized roaming (GUI)....742
Configure optimized roaming (CLI)....743

50 Cisco Flexible Radio Assignment....745
Flexible radio assignment actions....746
Configure FRA action in default RF profile (CLI)....746
Configure FRA action in 2.4-GHz RF profile (CLI)....747
Verify FRA action configuration....748

51 XOR Radio Support....749
Dual-band radios in Cisco AP models....750
Limitations....751
Configure default XOR radio support (CLI)....751

Configure XOR radio support for the specified slot number (GUI)....754
Configure XOR radio support for the specified slot number (CLI)....754
Verify XOR radio support....757

52 Cisco Receiver Start of Packet....759
Receiver start of packet detection threshold....760
Restrictions for Rx SOP....760
Permitted range for the Rx SOP threshold....760
Known behavior....760
Configure Rx SOP (CLI)....760
Customize RF profile (CLI)....761

53 Client Limit....763
Client limits....764
Limitations....764
Configure client limit per WLAN (GUI)....764
Configure client limit per WLAN (CLI)....765
Configure client limit per AP (GUI)....766
Configure client limit per AP (CLI)....767
Configure client limit per radio (GUI)....767
Configure client limit per radio (CLI)....768
Verify client limit....769

54 IP Theft....771
IP theft....772
Lower the idle timeout to prevent false IP theft....772
IP preference levels for IP theft detection....772
Configure IP theft (GUI)....772
Configure IP theft (CLI)....773
Configure the IP theft exclusion timer (CLI)....773
Add static entries for wired hosts (CLI)....774
Verify IP theft configuration....774
SAE client exclusion visibility....776
Configure client exclusion timeout (GUI)....777
Configure client exclusion timeout (CLI)....778
Verify client exclusion data....779

55 Unscheduled Automatic Power Save Delivery....781
Unscheduled automatic power save delivery overview....782
View unscheduled automatic power save delivery....782

56 Target Wake Time....783

Target wake time....784
Optimize power-saving with target wake time....785
Configure target wake time at radio level (CLI)....785
Enable target wakeup time on WLAN (CLI)....787
Disable target wakeup time on WLAN (CLI)....788
Configure target wake time (GUI)....789
Verify target wakeup time....789

57 Enabling USB Port on Access Points....791
USB port as power source for access points....792
Configure an AP profile (CLI)....792
Configure USB settings for an access point (CLI)....794
Configure USB settings for an access point (GUI)....795
USB configuration monitoring for access points (CLI)....796

58 Dynamic Frequency Selection....797
Dynamic frequency selection....798
Feature history for channel availability check (CAC)....798
Channel availability check....798
DFS verification....799
Zero wait dynamic frequency selection....800
Configure zero wait dynamic frequency selection globally....800
Configure zero wait dynamic frequency selection globally (CLI)....800
Enable zero wait dynamic frequency selection on a RF profile (GUI)....801
Enable zero wait dynamic frequency selection on a RF profile (CLI)....802
Zero wait dynamic frequency selection configuration verification....802

59 Cisco Access Points with Tri-Radio....805
Cisco access points with tri-radio....806
Guidelines and restrictions for tri-radio access points....807
Configure tri-radio for AP (GUI)....808
Configure the tri-radio (CLI)....808
Configure 5-GHz dual radio mode for AP (GUI)....808
Configure the dual radio mode and enable slots (CLI)....809
Set radio roles for slots (CLI)....810
Configure the tri-radio dual radio role (CLI)....811
Tri-radio configuration verification on the controller....811

60 Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard....813
Cisco Catalyst Center assurance Wi-Fi 6 dashboard....814
Configure Cisco Catalyst Center assurance Wi-Fi 6 dashboard parameters (CLI)....815
AP DFS counter verification (CLI)....817
Wi-Fi 6 access point parameter verification....817

61 Antenna Disconnection Detection....819
Antenna disconnection detection....820
Limitations....820
How antenna disconnection detection works....821
Configure antenna disconnection detection....821
Configure antenna disconnection detection using GUI....823
Detect broken antenna using SNMP trap (CLI)....823
Detect broken antenna using SNMP trap (GUI)....824
Verify antenna disconnection detection (Reference)....824
Verify antenna disconnection detection (GUI)....825

62 Neighbor Discovery Protocol Mode on Access Points....827
NDP mode....828
Configuration Tasks....829
Configure RRM NDP mode (GUI)....829
Configure the NDP mode (CLI)....830
Configure the NDP Type (CLI)....830
Configure NDP mode in the RF profile (GUI)....831
Configure NDP mode in the RF profile (CLI)....831
Monitor radio statistics and NDP using GUI....832
Verify NDP mode....833

63 6-GHz Band Operations....837
6-GHz Band Support....838
Feature history....838
Configure preferred scanning channels in the RF profile (GUI)....838
Configure preferred scanning channels in RF profile (CLI)....838
Configure broadcast probe response in RF profile (GUI)....839
Configure broadcast probe response in RF profile (CLI)....840
Configure FILS discovery frames in RF profile (GUI)....840
Configure FILS discovery frames in RF profile (CLI)....841
Configure multi BSSID profile (GUI)....842
Configure multi BSSID profile (CLI)....842
Configure multi BSSID in RF profile (GUI)....843
Configure multi BSSID in RF profile (CLI)....843
Configure dynamic channel assignment freeze (CLI)....844
6-GHz client steering....844
Configure 6-GHz client steering in global configuration mode (GUI)....845
Configure 6-GHz client steering in global configuration mode (CLI)....845
Configure 6-GHz client steering on WLAN (GUI)....846
Configure 6-GHz client steering on WLAN (CLI)....847
Verify 6-GHz client steering....847

Part VII: Network Management.....849

64 AP Packet Capture.....851

AP client packet capture.....852
Limitations of AP client packet capture.....852
Enable packet capture (GUI).....852
Enable packet capture (CLI).....853
Create AP packet capture profile and map to an AP join profile (GUI).....853
Create AP packet capture profile and map to an AP join profile.....854
Start or stop packet capture.....855

65 DHCP Option82.....857

DHCP Option 82.....858
Configure DHCP Option 82 format.....859
Configure DHCP Option 82 global interface.....861
Configure DHCP Option 82 globally through server override (CLI).....861
Configure DHCP Option 82 through server override (CLI).....861
Configure DHCP Option 82 globally through different SVIs (GUI).....862
Configure DHCP Option 82 globally through different SVIs (CLI).....863
Configure DHCP Option 82 through a VLAN interface.....863
Configure DHCP Option 82 through option-insert command (CLI).....863
Configure DHCP Option 82 through server-ID-override command (CLI).....865
Configure DHCP Option 82 through a subscriber-ID (CLI).....866
Configure DHCP Option 82 through server-ID-override and subscriber-ID commands (CLI).....867
Configure DHCP Option 82 through different SVIs (CLI).....869
AP DHCP Option 82 support on FlexConnect local switching mode.....870
Configure AP DHCP Option82 support.....870
Verify AP DHCP Option82 support.....871

66 RADIUS Authentication and Accounting.....873

RADIUS realms.....874
Enable RADIUS realm.....875
Configure realm to match the RADIUS server for authentication and accounting.....875
Configure AAA policy for WLANs.....876
Verify RADIUS-realm configuration.....879
RADIUS accounting of AP events.....880
Configure accounting method-list for an AP profile.....881
Verify AP accounting information.....882
Configure AAA accounting using default method list (CLI).....883
Configure HTTP command accounting using named method list (CLI).....883
RADIUS call station identifier.....884
Configure a RADIUS call station identifier.....886

RADIUS VSA....886
Create an attribute list....888
Map a AAA policy to WLAN policy profile....889
Map the WLAN policy profile to a WLAN....889

67 Cisco StadiumVision....891
Cisco StadiumVision....892
Configure Cisco StadiumVision parameters (GUI)....892
Configure Cisco StadiumVision parameters (CLI)....892
Verify StadiumVision configurations....893

68 Persistent SSID Broadcast....897
Persistent SSID broadcast....898
Configure persistent SSID broadcast (CLI)....898
Verify persistent SSID broadcast....899

69 Network Monitoring....901
Network monitoring 902
Status information received synchronously - configuration examples....902
Alarm and Event Information Received Asynchronously - Configuration Examples....904

70 Creating a Lobby Ambassador Account....907
Lobby ambassador account....908
Create a lobby ambassador user account....908
Create a lobby ambassador account (CLI)....910

71 Lobby Ambassador Account....911
Lobby ambassador account....912
Create a lobby ambassador user account....912
Create a lobby ambassador account (CLI)....914
Configure WLAN (GUI)....915
Client allowed list....916
Restrictions for client allowed list....916
Creating a client allowed list (GUI)....916
Manage guest users (GUI)....917
View a client allowed list....917

72 Guest User Accounts....919
Create guest user accounts....920
Create a guest user account (GUI)....920
Create a guest user account (CLI)....920
Verify guest user account....922

Assign username to guest users in a WLAN (CLI)....923

73 Link Local Bridging....925

Link local bridging....926

Guidelines and restrictions for link local bridging....927

Enable link local bridging per policy profile (GUI)....927

Enable link local bridging per policy profile (CLI)....927

Verify link local bridging....928

74 Web Admin Settings....931

Web admin settings....932

Configure HTTP/HTTPS access (GUI)....932

Configure HTTP trust point (GUI)....933

Configure NETCONF YANG (GUI)....934

Configure timeout policy (GUI)....934

Configure VTY (GUI)....935

Post-quantum cryptography support....935

75 Web UI Configuration Command Accounting in TACACS Server....939

Web UI configuration command accounting in TACACS+ server....940

Feature history for Web UI configuration command accounting in TACACS+ server....940

Guidelines for Web UI configuration command accounting in TACACS+ server....940

Configure AAA accounting using default method list (CLI)....940

Configure HTTP command accounting using named method list (CLI)....941

76 Embedded Packet Capture....943

Embedded packet capture....944

Feature history for embedded packet capture....944

Configure embedded packet capture (CLI)....944

Verify embedded packet capture....947

77 Layer 3 Access....951

Layer 3 access....952

Restrictions for Layer 3 access....952

Use cases for Layer 3 access....953

Enable Layer 3 access on policy profile (GUI)....954

Enable Layer 3 access on policy profile (CLI)....954

Configure a client gateway (GUI)....955

Configure a client gateway (CLI)....955

Enable internal DHCP with VRF (CLI)....956

Verify Layer 3 access details....958

OSPF protocols....960

Configure OSPF....960
Verify routing protocol details....964
PIM sparse mode....972
Enable multicast traffic without VRF (GUI)....973
Enable multicast traffic without VRF (CLI)....973
Enable multicast traffic with PIM-SSM (CLI)....975
Verify multicast traffic details....976
Network address translation (NAT)....979
Selective NAT support....980
Verify static NAT details....987
Verify dynamic NAT details....988
Verify NAT details....990
Verify NAT timeout details....991

78 IPv6 Layer 3 Access....993
IPv6 Layer 3 access....994
Feature history for IPv6 Layer 3 Access....994
DHCPv6 relay agents....994
How IPv6 Layer 3 client forwarding works....995
How DHCPv6 relay agents work....996
Guidelines for IPv6 Layer 3 forwarding....996
Restrictions for IPv6 Layer 3 forwarding....997
Use cases for IPv6 Layer 3 forwarding....997
Enable Layer 3 access on a wireless policy profile....997
Configure DHCPv6 relay or LDRA....998
Configure OSPFv3 for IPv6 Layer 3 access....1000
Configure IPv6 multicast routing for wireless clients....1000

Part VIII: System Management....1003

79 Network Mobility Services Protocol....1005
Network mobility services protocol....1006
Radioactive tracing for NMSP....1006
Enable NMSP on premises services (CLI)....1006
Modify the NMSP notification interval for clients, RFID tags, and rogues (CLI)....1007
Modify the NMSP notification threshold for clients, RFID tags, and rogues (CLI)....1008
Configure NMSP strong cipher (CLI)....1009
Verify NMSP settings....1009
Examples: NMSP settings configuration....1012
NMSP by AP groups with subscription list from CMX....1012
Verify NMSP by AP groups with subscription list from CMX....1013
Probe RSSI location....1014
Configure probe RSSI (CLI)....1015

RFID tag support....1016
Configure RFID tag support (CLI)....1016
Verify RFID tag support....1017

80 Application Visibility and Control....1021
Application visibility and control....1022
Guidelines for application visibility and control....1022
Prerequisites for application visibility and control....1023
Restrictions for application visibility and control....1023
Configure AVC....1024
Create a flow monitor (CLI)....1024
Configure a flow monitor (GUI)....1026
Create a flow record (CLI)....1026
Create a flow exporter (CLI)....1028
Configure a policy tag (CLI)....1030
Attach a policy profile to a WLAN interface (GUI)....1031
Attach a policy profile to a WLAN interface (CLI)....1031
Attach a policy profile to an AP (CLI)....1032
Verify the AVC configuration (CLI)....1033
Default DSCP on AVC....1034
Configuring default DSCP for AVC profile (GUI)....1034
Guidelines to configure default DSCP marking for unclassified AVC packets....1034
Create class map (CLI)....1035
Create policy map (CLI)....1035
AVC-based selective reanchoring....1037
Restrictions for AVC-based selective reanchoring....1037
Configure the flow exporter (CLI)....1037
Configure the flow monitor (CLI)....1038
Configure the AVC reanchoring profile (CLI)....1039
Configure the wireless WLAN profile policy (CLI)....1040
Verify AVC reanchoring....1041

81 Software-Defined Application Visibility and Control....1047
Software-defined application visibility and control....1048
Supported platforms for SD-AVC IPv6....1049
Enable software-defined application visibility and control on a WLAN (CLI)....1050
Configure software-defined application visibility and control global parameters (CLI)....1051
List of package files....1052
Verify SD-AVC controller connection status....1052
Verify SD-AVC details in AP....1053

82 Cisco Hyperlocation....1055
Cisco Hyperlocation....1056

Restrictions on Cisco Hyperlocation....1057
Configure Cisco Hyperlocation (GUI)....1057
Configure Cisco Hyperlocation (CLI)....1057
Verify Cisco Hyperlocation....1059
NTPS and BLE configuration....1062
Best practices for NTP configuration....1063
AP group NTP server....1064
Configure an AP group NTP server (CLI)....1065
Configure AP timezone (CLI)....1066
BLE concurrent scanning and beaconing....1066
Verify BLE concurrent scanning and beaconing....1067

83 FastLocate for Cisco Catalyst Series Access Points....1071
FastLocate....1072
Restriction for fabric deployments....1072
Supported access points....1072
FastLocate network components and functions....1073
Configure FastLocate (GUI)....1073
Verify FastLocate....1074

84 IoT Services Management....1077
IoT services management....1078
gRPC connection configuration details....1078
Enable the 802.15 radio (CLI)....1079
Configure the gRPC token (CLI)....1080
Enable gRPC in an AP profile (CLI)....1080
Verify BLE state and mode....1081
Verify BLE details....1081
Verify gRPC summary, status, and statistics....1082

85 IoT Module Management in the Controller....1085
IoT module management in the controller....1086
Enable a USB on the controller....1086
Verify the USB modules....1087

86 EDCA Parameters....1089
EDCA parameters....1090
Configure EDCA parameters (GUI)....1090
Configure EDCA parameters (CLI)....1090

87 Adaptive Client Load-Based EDCA....1093
Adaptive client load-based EDCA....1094

Use case for adaptive client load-based EDCA....1094
Restrictions for adaptive client load-based EDCA....1094
Configure adaptive client load-based EDCA (GUI)....1094
Configure adaptive client load-based EDCA (CLI)....1095
Verify adaptive client load-based EDCA configuration....1096

88 802.11 parameters and Band Selection....1099
Band select....1100
802.11 bands....1100
Restrictions for band selection, 802.11 bands, and parameters....1101
Configure band selection (GUI)....1101
Configure band selection (CLI)....1102
Configure the 802.11 bands (GUI)....1103
Configure the 802.11 bands (CLI)....1104
Configure a band-select RF profile (GUI)....1106
Configure a band-select RF profile (CLI)....1107
Configure 802.11n parameters (GUI)....1108
Configure 802.11n parameters (CLI)....1108
Configure 802.11h parameters (CLI)....1110
Verify configuration settings using band selection and 802.11 bands commands....1112
Example: view the configuration settings for the 6-GHz band....1112
Example: view the configuration settings for the 5-GHz band....1114
Example: view the configuration settings for the 2.4-GHz band....1115
Example: view the status of 802.11h parameters....1117
Example: verify the band-selection settings....1117
Examples: band selection configuration....1119
Examples: 802.11 bands configuration....1119
Examples: 802.11n configuration....1120
Examples: 802.11h configuration....1120

89 NBAR Protocol Discovery....1123
NBAR protocol discovery....1124
Restrictions of NBAR....1124
Configure NBAR protocol discovery (CLI)....1124
Verify protocol discovery statistics....1125

90 Conditional Debug, Radioactive Tracing, and Packet Tracing....1127
Conditional debugging....1128
Radioactive tracing....1128
Feature history for conditional debug and radioactive tracing....1129
Conditional debugging and radioactive tracing....1129
Location of tracefiles....1129
Configure conditional debugging (GUI)....1130

Configure conditional debugging (CLI)....1130
Radioactive Tracing for L2 Multicast....1132
Recommended workflow for trace files....1132
Copy tracefiles off the box....1133
Configuration examples for conditional debugging....1134
Verify conditional debugging....1134
Example: verify radioactive tracing log for SISF....1134
Packet tracing....1135
Configure conditional debugging packet tracing (CLI)....1136
Configure conditional debugging packet tracing per AP (CLI)....1137
Configure conditional debugging packet tracing per client (GUI)....1138
Configure conditional debugging packet tracing per client (CLI)....1138
Verify conditional debugging packet tracing configuration....1139
Wireless client debug bundle....1139
Types of logs collected....1140
Collect wireless client debug bundle (CLI)....1141

91 Aggressive Client Load Balancing....1143
Aggressive client load balancing....1144
Guidelines of aggressive client load balancing....1144
Restrictions of aggressive client load balancing....1144
Enable aggressive client load balancing (GUI)....1144
Configure aggressive client load balancing (GUI)....1145
Configure aggressive client load balancing (CLI)....1145

92 RF based Automatic AP Load Balancing....1147
RF based automatic AP load balancing....1148
Restrictions and guidelines for RF based automatic AP load balancing....1149
Configure RF based automatic AP load balancing....1149
Disable RF based automatic AP load balancing (CLI)....1151
Verify automatic WNCd load balancing....1152

93 Accounting Identity List....1155
Configure accounting identity list (GUI)....1156
Configure accounting identity list (CLI)....1156
Configure client accounting (GUI)....1156
Configure client accounting (CLI)....1157

94 Accounting Session ID....1159
Accounting session ID....1160
Configure an accounting session ID (CLI)....1160
Verify an account session ID....1162

95 Interim Accounting....1163
Interim accounting....1164
Disable interim accounting (CLI)....1164
Verify interim accounting....1165

96 Wireless Multicast....1167
Wireless multicast....1168
Multicast optimization....1169
IPv6 global policies....1169
Prerequisites for configuring wireless multicast....1169
Restrictions on configuring wireless multicast....1170
Configuring wireless multicast....1170
IPv6 snooping....1172
IPv6 device tracking....1173
IPv6 address glean....1174
Restrictions for IPv6 snooping....1174
IPv6 multicast over multicast....1175
Configure IPv6 multicast-over-multicast (GUI)....1176
Configure IPv6 multicast-over-multicast (CLI)....1176
Verify IPv6 multicast-over-multicast....1176
Verify the multicast connection between the controller and the AP....1177
Directed multicast service....1177
Configure directed multicast service (GUI)....1177
Configure directed multicast service (CLI)....1178
Verify the directed multicast service configuration....1179
Restrictions for wireless broadcast, non-IP multicast and multicast VLAN....1180
Configure non-IP wireless multicast (CLI)....1180
Configure wireless broadcast (GUI)....1181
Configure wireless broadcast (CLI)....1181
Configure multicast-over-multicast for AP multicast groups (CLI)....1182
Verify wireless multicast....1183
Multicast optimization....1183
Configure IP multicast VLAN for WLAN (GUI)....1184
Configure IP multicast VLAN for WLAN (CLI)....1184
Verify the multicast VLAN configuration....1185
Multicast filtering....1186
Supported L3 multicast report for filtering....1187
Configure multicast filtering (CLI)....1187
Verify multicast filtering....1188

97 Map-Server Per-Site Support....1189
Map server per site support....1190

Configure the default map server (GUI)....1190
Configure the default map server (CLI)....1191
Configure a map server per site (GUI)....1191
Configure a map server per site (CLI)....1192
Create a map server for each VNID (GUI)....1192
Create a map server for each VNID (CLI)....1193
Create a fabric profile and associate a tag and VNID (GUI)....1193
Create a fabric profile and associate a tag and VNID (CLI)....1194
Verify the map server configuration....1194

98 Volume Metering....1197
Volume metering....1198
Configure volume metering (CLI)....1198

99 Enabling Syslog Messages in Access Points and Controller for Syslog Server....1201
Syslog messages in access points and controllers....1202
Syslog support for client state change....1202
Configure syslog support for client state change (CLI)....1203
Sample syslogs....1203
Configure the syslog server for the controller (GUI)....1204
Configure a syslog server for a controller (CLI)....1205
AP logging to the in-memory buffer and flash....1207
AP logging to terminal....1207
Configure AP logging to a syslog server....1208
Configure a syslog server for an AP profile (CLI)....1209
Configure the AP syslog settings (GUI)....1210
Verify syslog server configurations....1211

100 Login Banner....1215
Login banners....1216
Configure a login banner (GUI)....1216
Configure a login banner (CLI)....1216

101 Wi-Fi Alliance Agile Multiband 1219
Wi-Fi alliance agile multiband....1220
Components of a Wi-Fi Agile Multiband topology....1220
Supported MBO components....1221
Limitations of MBO....1222
Configure MBO on a WLAN (CLI)....1222
Verify MBO configuration....1224

102 SNMP Traps....1227
SNMP trap configuration....1228
Configure SNMP Traps (GUI)....1228
Enable AP Traps (CLI)....1229
Enable wireless client traps (CLI)....1230
Enable Mesh Traps (CLI)....1230
Enable RF Traps (CLI)....1231
Enable rogue, mobility, RRM, and general traps (CLI)....1232
Verify SNMP wireless traps....1233

103 Disabling Clients with Random MAC Address....1235
Random MAC addresses....1236
Configure random MAC address denial (CLI)....1236
Verify denial of clients with a random MAC address....1237

104 Dataplane Packet Logging....1239
Dataplane packet logs....1240
Enable or disable debug level (CLI)....1240
Enable packet logging in the global and filtered buffers in the ingress-path (CLI)....1241
Enable packet logging in global and filtered buffers for the punt-inject path (CLI)....1242
Verify dataplane packet logging....1243
Clear logs and conditions in global and filtered trace buffers....1244

105 Streaming Telemetry....1245
Streaming telemetry....1246
Gather points....1246
Subscription....1247
Transport....1248
Scale considerations....1248
Session....1248
Configure telemetry on controllers....1250
On-Change Telemetry Support....1259
Supported XPaths for on-change subscription....1259
Troubleshooting Telemetry Support....1263
Client event and SSID telemetry filters....1266
How the Client Event and SSID Telemetry Filter Works....1266
Restrictions for Cisco Catalyst Center client event and SSID telemetry filter....1268
Configure Client Event and SSID Telemetry Filters....1268
Enable iCAP filter on AP (CLI)....1268
Disable client telemetry data for a WLAN (YANG)....1269
Verify client telemetry data for WLAN....1269

106 Application Performance Monitoring....1271
APM....1272
Restrictions....1272
Configure APM....1273
Create a flow monitor....1273
Create a wireless WLAN profile policy....1274
Create a policy tag....1276
Attach the policy profile to an AP....1276
Verify APM....1277

107 Wireless Clients Threshold Warning....1279
Wireless client threshold warnings....1280
Configure a warning period (CLI)....1280
Configure the client threshold (CLI)....1281

108 Intelligent Capture Hardening....1283
Cisco Intelligent Capture (iCAP) feature and enhancements....1284
Anomaly detection....1284
RF statistics....1285
Configure anomaly detection in AP profile (CLI)....1285
Configure anomaly detection in an AP (CLI)....1286
Verify anomaly detection and RF statistics....1287

109 Amazon S3 Support....1289
Amazon S3 support....1290
Restrictions and guidelines....1290
Configure Amazon S3 support (CLI)....1290
Verify Amazon S3 support....1292

110 Amazon Web Services CloudWatch....1295
Amazon Web Services CloudWatch Support....1296
Benefits of Amazon web services CloudWatch service....1296
Configure an AWS CloudWatch Profile (CLI)....1297
Verify AWS CloudWatch configuration....1299

111 Kernel Minidump and Trustzone Upgrade....1301
Kernel minidump and trust zone upgrade....1302
Configure the Minidump from the AP (CLI)....1303
Configure the minidump from the controller (CLI)....1304
Verify minidump configuration....1305

Part IX: Cloud Services....1307

112 Cisco Spaces....1309

Cisco Spaces....1310

Configure Cisco Spaces....1310

Verify Cisco Spaces configuration....1311

113 Sensor Connect backup and restore....1313

Sensor Connect backup and restore....1314

Feature history for Sensor Connect backup and restore....1314

Guidelines for Sensor Connect backup and restore....1315

Restrictions for Sensor Connect backup and restore....1315

Backup the Sensor Connect application....1315

Restore the Sensor Connect application....1316

Sensor Connect launch and Day-0 configuration....1316

114 AP and Sensor Connect support for full filtering....1319

AP and Sensor Connect support for full filtering....1320

Feature history for AP and Sensor Connect support for full filtering....1320

Guidelines for BLE full filtering....1320

Launch Sensor Connect from the Catalyst 9800 controller....1321

115 Using Cloud Monitoring as a Solution for Network Monitoring....1323

Cloud monitoring....1324

When to use cloud monitoring....1324

Cloud monitoring features....1324

Prerequisites for cloud monitoring....1325

Enable cloud monitoring (GUI)....1325

Enable cloud monitoring (CLI)....1325

Onboard the controller using Cisco Meraki dashboard....1326

Verify cloud monitoring....1326

Troubleshoot cloud monitoring....1327

116 Wireless Active Testing with ThousandEyes....1329

Wireless active testing (WAT)....1330

Feature history for wireless active testing with ThousandEyes....1330

Supported controller and AP platforms....1330

Supported security types....1331

Guidelines of wireless active testing....1332

Configure wireless active testing (GUI)....1333

Configure wireless active testing (CLI)....1333

Configure HTTP(S) proxy for WAT (GUI)....1334
Configure HTTP(S) proxy for WAT (CLI)....1334
Configure WAT radio selection and tag the RF profile (GUI)....1335
Configure wireless active testing radio selection (CLI)....1336
Enable WAT management for an individual AP (GUI)....1337
Enable WAT management for an individual AP (CLI)....1337
Enable WAT management for multiple APs using location (GUI)....1338
Enable WAT management for multiple APs using location (CLI)....1339
Enable WAT management for multiple APs using filter (GUI)....1340
Enable WAT management for multiple APs using filter (CLI)....1340
Verify wireless active testing....1341

117 Wireless Active Testing SCEP support....1343
Wireless Active Testing SCEP support....1344
Feature history for Wireless Active Testing SCEP support....1344
SCEP enrollment for Wireless Active Testing....1344
Guidelines for Wireless Active Testing SCEP....1345

Part X: Security....1347

118 MAC Filtering....1351
MAC Filtering....1352
Configuring MAC Filtering for Local Authentication (CLI)....1353
Configuring MAC Filtering (GUI)....1355
Configuring MAB for External Authentication (CLI)....1355

119 Web-Based Authentication....1359
Local web authentication....1360
How local web authentication works....1361
Restrictions....1362
Roles of devices in local web authentication....1362
Banner messages for local web authentication....1363
Authentication states in customized local web authentication....1365
How to configure local web authentication....1366
Configuration examples for local web authentication....1391
External Web Authentication....1397
Configure EWA with single WebAuth server address and default ports (80/443) (CLI)....1397
Configure EWA with multiple web servers and/or ports different than default (80/443)....1399
Configure wired guest EWA with multiple web servers, ports different than default (80/443)....1402
Authenticating sleeping clients....1403
Guidelines for mobility scenarios....1404
Restrictions on authenticating sleeping clients....1404
Configure authentication for sleeping clients (GUI)....1405

Configure authentication for sleeping clients (CLI)....1405
Sleeping Clients With Multiple Authentication....1406
Mobility support for sleeping clients....1406
Supported combinations of multiple authentications....1407
Configure WLAN for 802.1X and local web authentication....1407
Configure a WLAN for MAC authentication bypass and LWA....1408
Configure a WLAN for local web authentication and MAC filtering....1410
Configure a PSK + LWA in a WLAN....1411
Configure a sleeping client....1413
Verify a sleeping client configuration....1414
Multiple Authentication Combinations with 802.1X and LWA....1414
Multiauthentication combinations with 802.1X authentication and local web authentication....1414
Limitations for multi authentication combination of 802.1X and local web authentication....1415
Enable the multiauthentication combinations of 802.1X authentication and local web authentication (CLI)....1415
Verify multiauthentication combination with 802.1X authentication and local web authentication...1416
Title....1416

120 Central Web Authentication....1417
Central web authentication....1418
How to configure ISE....1419
How to configure central web authentication on the controller....1422

121 Private Shared Key....1433
Private preshared keys....1434
Limitations....1434
How identity PSK authentication works....1434
Configure a PSK in a WLAN....1435
Configure a PSK in a WLAN using GUI....1437
Apply a policy profile to a WLAN (GUI)....1438
Apply a policy profile to a WLAN using CLI....1438
Verify a private PSK....1439

122 Multi-Preshared Key....1443
Multi-preshared key....1444
Restrictions....1445
Procedures....1446
Configure a multi-preshared key (GUI)....1446
Configure a multi-preshared key (CLI)....1448
Verify multi-PSK configurations....1450

123 Wireless AAA Authentication Survivability Cache....1453
Wireless AAA authentication survivability cache....1454

Feature history for wireless AAA authentication survivability cache....1454
Configure wireless AAA authentication survivability cache 1455
RADIUS configuration for MSCHAPv2....1462
Configure EAP-TLS on ISE....1463
Verify wireless AAA authentication survivability cache....1463

124 Wi-Fi Protected Access 3....1465
Overview of WPA3....1466
Simultaneous Authentication of Equals....1466
Opportunistic Wireless Encryption....1467
Hash-to-Element (H2E)....1468
YANG (RPC model)....1468
Transition Disable....1470
WPA3 SAE iPSK....1471
WPA3 Configuration Tasks....1471
Configure SAE (WPA3+WPA2 mixed mode)....1471
Configure WPA3 enterprise (GUI)....1474
Configure WPA3 enterprise....1474
Configure WPA3 OWE....1476
Configure WPA3 OWE transition mode (GUI)....1478
Configure WPA3 OWE transition mode....1478
Configure WPA3 SAE (GUI)....1480
Configure WPA3 SAE....1481
Configure a WPA3 SAE iPSK WLAN profile (CLI)....1483
Configure a policy profile with AAA override and VLAN assignment (CLI)....1485
Configure a passphrase in a client authorization policy in the RADIUS server(GUI) 1486
Configure WPA3 SAE H2E (GUI)....1486
Configure WPA3 SAE H2E (CLI)....1487
Configure WPA3 WLAN for Transition Disable....1489
Configure anti-clogging and SAE retransmission (GUI)....1490
Configure anti-clogging and SAE retransmission (CLI)....1491
Verify WPA3 SAE and OWE....1492
Verify WPA3 SAE H2E support in WLAN....1494
Verify WPA3 transition disable in WLAN....1500

125 WPA3 Security Enhancements for Access Points....1505
WPA3 security enhancements for APs....1506
Restrictions....1510
GCMP-256 Cipher and SuiteB-192-1X AKM....1510
SAE-EXT-KEY support....1513
AP beacon protection....1521
Multiple cipher support per WLAN....1523
OWE support with GCMP-256 cipher....1526

126 IP Source Guard....1529
IP source guard....1530
Configure IP source guard (GUI)....1530
Configure IP source guard (CLI)....1530

127 Traffic Filtering on AP by Source IP ACL....1533
Traffic filtering on AP by source IP ACL....1534
Feature History for Traffic Filtering on AP by Source IP ACL....1534
Configure AP management ACL on controller....1534
Verify mapped ACLs....1537

128 802.11w....1539
Protected management frames with 802.11w....1540
Integrity Group Temporal Key (IGTK)....1541
Broadcast or multicast integrity protocol (BIP)....1542
SA teardown protection....1542
Prerequisites for 802.11w....1543
Restrictions for 802.11w....1543
Configure 802.11w....1543
Configure 802.11w (GUI)....1543
Configure 802.11w (CLI)....1544
Disable 802.11w....1545
Monitor 802.11w....1546

129 Management Frame Protection....1549
Information About Management Frame Protection....1550
Restrictions for Management Frame Protection....1551
Configure Management Frame Protection (CLI)....1551
Verifying Management Frame Protection Settings....1552

130 IPv4 ACLs....1555
Network security with ACLs....1556
ACL overview....1556
Supported ACLs....1557
ACEs and fragmented and unfragmented traffic....1559
Standard and extended IPv4 ACLs....1560
Hardware and software treatment of IP ACLs....1564
IPv4 ACL interface considerations....1565
Restrictions for configuring IPv4 access control lists....1566
How to configure ACLs....1567
Configure IPv4 ACLs (GUI)....1567

Configure IPv4 ACLs....1567
Create a numbered standard ACL (GUI)....1567
Create a numbered standard ACL (CLI)....1568
Create a numbered extended ACL (GUI)....1569
Create a numbered extended ACL (CLI)....1570
Create named standard ACLs (GUI)....1573
Create named standard ACLs (CLI)....1573
Create extended named ACLs (GUI)....1574
Create extended named ACLs (CLI)....1575
Apply an IPv4 ACL to an interface (GUI)....1576
Apply an IPv4 ACL to an interface (CLI)....1577
Apply ACL to policy profile (GUI)....1578
Apply ACL to policy profile (CLI)....1578
Configuration examples for ACLs....1579
Examples: including comments in ACLs....1579
Examples: apply an IPv4 ACL to a policy profile in a wireless environment....1579
IPv4 ACL Configuration Examples....1580
Monitor IPv4 ACLs....1583

131 Downloadable ACL....1585

Downloadable ACLs....1586
Feature history for downloadable ACL....1586
Scale considerations for downloadable ACL....1587
Restrictions for downloadable ACL....1587
Configuring dACL name and definition in Cisco ISE....1588
Configure dACL in a controller (CLI)....1588
Configure explicit authorization server list (CLI)....1589
Verify dACL configuration....1590

132 DNS-Based Access Control Lists....1593

DNS-based access control lists....1594
Restrictions on DNS-based access control lists....1595
Define ACLs....1596
Methods for applying ACLs....1596
Configure ISE for central web authentication (GUI)....1597
View DNS-based access control lists....1598
Configuration examples for DNS-based access control lists....1598
Verify DNS snoop agent (DSA)....1599
URL filters....1601
FlexConnect mode....1602
Local mode....1604
Configure ISE for central web authentication....1606
Create authorization profiles (GUI)....1607
Map authorization profiles to authentication rule (GUI)....1607

Map authorization profiles to authorization rule (GUI)....1608
FlexConnect client IPv6 support with WebAuth pre and post ACL....1608
FlexConnect client IPv6 support with WebAuth pre and post ACL....1608
Enable pre-authentication ACL for LWA and EWA (GUI)....1609
Enable pre-authentication ACL for LWA and EWA (CLI)....1610
Enable post-authentication ACL for LWA and EWA (GUI)....1611
Enable post-authentication ACL for LWA and EWA (CLI)....1611
Enable DNS ACL for LWA and EWA (GUI)....1612
Enable DNS ACL for LWA and EWA (CLI)....1612
Verify FlexConnect client IPv6 support with WebAuth pre and post ACL....1613

133 Allowed List of Specific URLs....1615
Allowed lists of specific URLs....1616
Add URL to allowed list....1616
Portal resolving to multiple IP addresses....1618
Verify URLs on the allowed list....1618

134 Cisco Umbrella WLAN....1621
Cisco Umbrella WLAN....1622
Register Controller to Cisco Umbrella account....1622
Restrictions for Umbrella WLAN....1623
Configure Cisco Umbrella WLAN....1624

135 RADIUS Server Load Balancing....1639
RADIUS server load balancing....1640
Prerequisites for RADIUS server load balancing....1642
RADIUS server load balancing restrictions....1642
Enable load balancing for a named RADIUS server group (CLI)....1643

136 AAA Dead-Server Detection....1645
AAA dead-server detection....1646
Prerequisites for AAA dead-server detection....1646
Restrictions for AAA dead-server detection....1647
Configure AAA dead-server detection (CLI)....1647

137 ISE Simplification and Enhancements....1651
Security utilities configuration options....1652
Configure multiple RADIUS servers....1653
Verify AAA and Radius server configurations....1653
Captive bypassing....1654
Configure captive bypassing for WLAN in LWA and CWA (GUI)....1655
Configure captive bypassing for WLAN in LWA and CWA....1656

DHCP option 55 and 77 parameters....1657
Configure the DHCP options 55 and 77 to ISE using the GUI....1657
Configure the device to send DHCP options 55 and 77 to ISE (CLI)....1658
Configure the EAP request timeout using the GUI....1659
Configure EAP request timeout....1659
Configure the EAP request timeout in wireless security....1660
Captive portals....1661
Configure captive portal (GUI)....1661
Configure captive portal....1662
Example: Captive portal configuration....1665

138 RADIUS DTLS....1667
RADIUS DTLS....1668
Requirement: Port RADIUS DTLS support to BINOS platforms....1669
Configure RADIUS DTLS server (CLI)....1669
Configure DTLS Dynamic Author (CLI)....1677
Enable DTLS for client (CLI)....1678
Verify RADIUS DTLS server configuration....1682
Clear RADIUS DTLS specific statistics....1682

139 Policy Enforcement and Usage Monitoring....1685
Policy enforcement and usage monitoring....1686
Configure policy enforcement and enable CoA (CLI)....1686
Example: Configure policy enforcement and usage monitoring....1687
Verify policy usage and enforcement....1688

140 Local Extensible Authentication Protocol....1689
Local EAP....1690
Restrictions for local EAP....1690
Configure local EAP profile (CLI)....1690
Configure local EAP profile (GUI)....1691
Configure AAA authentication (GUI)....1692
Configure AAA authorization method (GUI)....1692
Configure AAA authorization method (CLI)....1693
Configure local advanced methods (GUI)....1694
Configure WLAN (GUI)....1694
Configure WLAN (CLI)....1695
Create a user account (CLI)....1696
Attach a policy profile to a WLAN interface (GUI)....1697
Deploy policy tag to access points (GUI)....1698

141 Local EAP Ciphersuite....1699
Local EAP Ciphersuite....1700

Restrictions for Local EAP Ciphersuite....1701
Configure Local EAP Ciphersuite (CLI)....1701

142 Authentication and Authorization Between Multiple RADIUS Servers....1703
Authentication and authorization between multiple RADIUS servers....1704
Configure explicit authentication and authorization server list (GUI)....1704
Configure explicit authentication server list (GUI)....1705
Configure explicit authentication server list (CLI)....1705
Configure explicit authorization server list (GUI)....1707
Configure explicit authorization server list (CLI)....1707
Configure authentication and authorization list for 802.1X security (GUI)....1710
Configure authentication and authorization list for 802.1X security (CLI)....1710
Configure web authentication for WLAN with split authentication and authorization servers....1711
Configure authentication and authorization list for web authentication (GUI)....1711
Configure authentication and authorization list for web authentication (CLI)....1712
Verify split authentication and authorization configuration....1713
Configuration examples....1714
RADIUS Message-Authenticator support for non-EAP requests....1715
Configure RADIUS Message-Authenticator support for non-EAP requests (CLI)....1716

143 CUI Information in RADIUS Accounting....1717
CUI information in RADIUS accounting request....1718
Prerequisites and restrictions....1718
Add CUI information in a RADIUS accounting request....1718
Verify CUI information in a RADIUS accounting request....1719

144 Secure LDAP....1721
Lightweight Directory Access Protocol (LDAP)....1722
SLDAP prerequisite....1723
SLDAP restrictions....1723
Configure SLDAP (CLI)....1723
Configure a AAA server group (GUI)....1725
Configure a AAA server group (CLI)....1726
Configure search and bind operations for authentication requests (CLI)....1727
Configure a dynamic attribute map on a SLDAP server (CLI)....1728
Verify the SLDAP configuration....1729

145 Network Access Server Identifier....1731
Network Access Server Identifier (NAS-ID)....1732
Create a NAS ID policy (GUI)....1732
Create a NAS ID policy (CLI)....1733
Attach a policy to a tag (GUI)....1734
Attach a policy to a tag (CLI)....1734

Verify the NAS ID configuration....1735

146 Locally Significant Certificates....1737

Locally significant certificates....1738
Certificate provisioning in controllers....1738
How device certificate enrollment works....1739
How certificate provisioning works on lightweight APs....1740
Restrictions for locally significant certificates....1740
Provisioning locally significant certificates....1741
Configure RSA key for PKI trustpoint....1741
Configure PKI trustpoint parameters....1742
Authenticate and enroll a Public Key Infrastructure (PKI) trustpoint (GUI)....1744
Authenticate and enroll the PKI trustpoint with CA server (CLI)....1744
Configure AP join attempts with LSC certificate....1747
Configure AP join attempts with LSC certificate (CLI)....1747
Configure subject-name parameters in LSC certificate....1748
Configure key size for LSC certificate....1748
Configure trustpoint for LSC provisioning on an AP....1749
Configure an AP LSC provision list (GUI)....1750
Configure an AP LSC provision list (CLI)....1750
Configure LSC provisioning for all the APs (GUI)....1751
Configure LSC provisioning for all APs (CLI)....1752
Configure LSC provisioning for the APs in the provision list....1753
Import a CA certificate to the trustpool (GUI)....1753
Import a CA certificate to the trustpool....1754
Clean the CA certificates imported in trustpool (GUI)....1755
Clean CA certificates imported in trustpool (CLI)....1755
Create a new trustpoint dedicated to a single CA certificate....1756
Verify LSC configuration 1757
Configure management trustpoint to LSC....1758
Configure management trustpoint to LSC (CLI)....1758
AP certificate renewal (LSC)....1759
AP certificate renewal (LSC)....1759
Benefits of AP certificate renewal (LSC)....1759
Requirements for AP certificate renewal (LSC)....1759
Restrictions for AP certificate renewal (LSC)....1760
Configure AP certificate auto-renewal (LSC) (GUI)....1760
Configure AP certificate renewal (LSC) (CLI)....1761
Configure forced renewal of AP certificate (LSC) for individual or multiple APs (GUI)....1762
Configure forced renewal of AP Certificate (LSC) based on site tag (GUI)....1763
Configure forced renewal of AP Certificate (LSC) based on site tag (CLI)....1763
Configure forced renewal of all APs (GUI)....1764
Verify AP certificate renewal (LSC)....1764
MIC and LSC APs joining the controller....1765

Support for MIC and LSC APs joining the controller....1765
Recommendations and limitations....1766
MIC and LSC access point authentication....1766
Configure LSC on the controller (CLI)....1767
Enable the AP certificate policy on the APs (CLI)....1767
Configure the AP policy certificate (GUI)....1769
Configure the allowed list of APs to join the controller (CLI)....1769
Verifying the configuration status....1770
LSC fallback APs....1771
LSC fallback APs....1771
Troubleshoot LSC fallback state....1771
Recover from LSC fallback....1773
Configuring controller self-signed certificate for wireless AP join....1773
Use cases for controller self-signed certificate for wireless AP join....1774
Prerequisites for controller self-signed certificate for wireless AP join....1774
Configure clock calendar (CLI)....1775
Enable HTTP server using CLI....1775
Configure CA server (CLI)....1776
Configure trustpoint (CLI)....1779
Authenticate and enroll the PKI trustpoint with CA server....1781
Tag wireless management trustpoint name....1782
Disable PKI server....1782
Verify controller certificates for wireless AP join....1783

147 Public Key Infrastructure Management....1785
About PKI management (GUI)....1786
Restriction: CSR generation on the GUI may hang indefinitely....1786
Configuration Tasks....1787
Authenticate and enroll a Public Key Infrastructure (PKI) trustpoint (GUI)....1787
Generate an AP self-signed certificate (GUI)....1787
Add the CA server (GUI)....1788
Add an RSA or EC Key for PKI trustpoint (GUI)....1788
Add and manage certificates 1789

148 Controller Self-Signed Certificate for Wireless AP Join....1793
Controller self-signed certificates for wireless AP Join....1794
Use cases for controller self-signed certificate for wireless AP join....1794
Requirement: Use minimum RSA key size for DTLS connections....1794
Prerequisites for controller self-signed certificate for wireless AP join....1795
Configure clock calendar (CLI)....1795
Enable HTTP server using CLI....1796
Configure CA server (CLI)....1797
Configure trustpoint (CLI)....1799
Authenticate and enroll the PKI trustpoint with CA server....1801

Tag wireless management trustpoint name....1802
Disable PKI server....1803
Verify controller certificates for wireless AP join....1804

149 Managing Rogue Devices....1807
Rogue devices and detection....1808
Restrictions on rogue detection....1808
Rogue AP containment and attack signatures....1808
Cisco Prime Infrastructure interaction and rogue detection....1809
Rogue containment (Protected Management Frames (PMF) enabled)....1810
Off-channel PMF rogue containment....1810
AP impersonation detection....1811
Rogue detection security level....1812
Configuring rogue detection (GUI)....1814
Configure rogue detection (CLI)....1815
Configure RSSI deviation notification threshold for rogue APs (CLI)....1816
Configure management frame protection (GUI)....1817
Configure Management Frame Protection (CLI)....1817
Enable AP authentication....1818
Configure off-channel PMF rogue containment (GUI)....1819
Configure off-channel PMF rogue containment (CLI)....1819
Verify management frame protection....1820
Verify rogue events....1821
Verify rogue detection....1821
Verify off-channel PMF rogue containment....1823
Examples: rogue detection onfiguration....1823
Configure rogue policies (GUI)....1824
Configure rogue policies (CLI)....1825
Wireless Service Assurance (WSA) rogue events....1827
Wireless service assurance rogue events....1827
Monitor wireless service assurance rogue events....1828
Rogue AP scale modes per class....1829
Feature history for rogue full scale quotas and priorities....1830
Advantages and disadvantages of role-scale modes....1830
Configure rogue AP scale (CLI)....1831
Verify rogue scale details....1832
Rogue PMF containment....1833
Enable rogue PMF containment....1833
Verify PMF containment....1834

150 Classifying Rogue Access Points....1837
Rogue AP classifications....1838
Rogue containment methods....1839
Guidelines and restrictions for classifying Rogue APs....1840

How to classify rogue APs....1841
Monitor rogue classification rules....1846
Examples: classifying rogue AP....1847

151 Advanced WIPS....1849

Advanced WIPS....1850
Advanced WIPS signatures and definitions....1850
Guidelines and Restrictions....1852
Enable advanced WIPS....1853
Syslog messages for advanced WIPS....1853
Advanced WIPS solution components and capabilities....1854
Supported modes and platforms....1855
Enable advanced WIPS (GUI)....1855
Enable advanced WIPS (CLI)....1855
Configure syslog threshold for advanced WIPS (CLI)....1857
View advanced WIPS alarms (GUI)....1857
Verify advanced WIPS....1858
Verify syslog configuration for advanced WIPS....1859

152 Cisco TrustSec....1861

Cisco TrustSec....1862
Cisco TrustSec features....1863
Configure a device SGT manually (CLI)....1864
Configure ISE for TrustSec (CLI)....1865
Verify Cisco TrustSec configuration....1866
Security Group Access Control List (SGACL)....1868
Guidelines and restrictions of SGACL....1869
Enable SGACL on the AP (GUI)....1870
Enable SGACL on the AP (CLI)....1870
Policy enforcement....1871
Inline tagging....1874
SGACL and environment data download over REST....1876
Cisco TrustSec - ISE communication over IPv6 1889
Limitations of IPv4....1889
Configure ISE for TrustSec (CLI)....1889
Configure TrustSec SXP with IPv6 (GUI)....1891
Configure TrustSec SXP with IPv6....1892
Verify Cisco TrustSec PAC over IPv6 RADIUS....1893
TrustSec IP-SGT High Availability binding....1894
Verify TrustSec IP-SGT High Availability binding support....1895

153 SGT Inline Tagging and SXPv4....1899

SGT inline tagging on AP and SXPv4....1900

Create an SXP profile....1900
Configure SGT inline tagging on APs....1901
Configure an SXP connection (GUI)....1901
Configure an SXP connection....1902
Verify SGT push to APs....1903

154 Ciphersuites for CAPWAP-DTLS....1907
Default ciphersuites supported for CAPWAP-DTLS....1908
Configure multiple ciphersuites (CLI)....1908
Set server preference (CLI)....1909
Verify operational ciphersuites and priority....1910

155 Configure Secure Shell 1911
SSH....1912
SSH and device access....1912
SSH servers and integrated clients....1912
SSH configuration guidelines....1913
SCP....1913
Secure copy protocol....1914
SFTP support....1914
Prerequisites for configuring SSH....1914
Restrictions for configuring SSH....1915
Set up the device to run SSH....1915
Configure the SSH server....1917
Monitor the SSH configuration and status....1919

156 MACsec support on APs....1921
MACsec support on AP 1922
Common MACsec terminology....1923
Supported AP....1923
MACsec modes, authentication options, and supported ciphers....1923
Restrictions....1924
MACsec failover mechanism....1924
Configuring MACsec with PSK....1925
Configuring MACsec with IEEE 802.1X....1932
Auto MACsec for wireless APs....1937
Benefits of auto MACsec....1938
Enable auto MACsec (GUI)....1938
Enable auto MACsec in AP join profile (CLI)....1939
Verify auto MACsec....1939
Recovery for Auto MACsec....1940

157 FIPS....1943

Federal Information Processing Standard (FIPS)....1944
Guidelines and restrictions for FIPS....1944
FIPS self-tests....1945
Configure FIPS (CLI)....1946
How FIPS configuration works in high availability setups....1947
Verify FIPS configuration....1949
Common criteria....1949
Configure the common criteria (CLI)....1950
Verify CC configuration....1951
Check points for CC mode operation....1951
TLS signature algorithm enhancements for NDcPP v3.0e....1953
Signature algorithms and ciphersuites in TLS and DTLS applications....1954
Configure syslog TLS profile ciphersuites (CLI)....1957
Configure HTTP secure ciphersuites....1958
Verify Syslog TLS profile....1958
Verify HTTP client and server applications....1958
HTTPS server security considerations with NDcPP 4.0....1959
Best practices for HTTPS server security....1960
Configure HTTP server security settings (CLI)....1960
Configure HTTP client security settings (CLI)....1961

158 Internet Protocol Security....1963
Internet Protocol Security (IPsec)....1964
IKEv1 transform sets....1964
Configure IPsec using IKEv1....1965
IKEv2 transform sets....1968
Configure IPsec using IKEv2....1968
IPsec transforms and lifetimes....1971
Use of X.509 with IKE version....1972
IPsec session interruption and recovery....1973
Example: Configure IPsec using ISAKMP....1973
Verify IPSec traffic....1973
Example: Configure IPsec using IKEv2....1975
Verify IPSec with IKEv2 traffic....1975

159 Transport Layer Security Tunnel Support....1979
Transport layer security tunnels....1980
Configure a transport layer security tunnel....1980
Transport layer security tunnel verification....1983

160 Configuring RFC 5580 Location Attributes....1987
RFC 5580 location attributes....1988
Location-capable attribute....1989

Restriction for configuring RFC 5580 location attributes....1990
Configure location delivery based on out-of-band agreement (CLI)....1990
Configure the location-capable attribute (CLI)....1990
Configure a civic profile (CLI)....1991
Configure a geo profile (CLI)....1993
Configure an operator name (CLI)....1994
Associate a location attribute with a user location (CLI)....1996
Associate the NAS location with location attributes (CLI)....1997
Verify RFC 5580 location attribute configuration....1998

161 IP MAC Binding....2001
IP MAC binding....2002
Use cases for no IP MAC binding....2002
Disable IP MAC binding (CLI)....2003
Verify IP MAC binding....2004

162 Disabling IP Learning in FlexConnect Mode....2005
Disabling IP learning in FlexConnect mode....2006
Restrictions for disabling IP learning in FlexConnect mode....2006
Disable IP learning in FlexConnect mode....2006
MAC entry verification from database....2007

163 Disabling Device Tracking to Support NAC Devices....2009
Disabling device tracking to support NAC devices....2010
Feature history for disable device tracking support for NAC devices....2010
Restrictions for disabling device tracking to support NAC devices....2010
Disable device tracking for wireless clients (CLI)....2011
Verify ARP broadcast....2012

164 Disabling IP Learning in Local Mode....2013
Disabling IP learning in local mode....2014
Restrictions for disabling IP learning in local mode....2014
Disable IP learning in local mode (CLI)....2015
Verify MAC entries database....2016
ARP broadcast verification....2016

165 Security-Enhanced Linux....2017
Security-Enhanced Linux....2018
Configure SELinux in the EXEC mode....2018
Configure SELinux in the global configuration mode....2019
Examples for SELinux....2020
SELINUX syslog message reference....2020

Verify count of denials....2021
Verify SELinux enablement....2022

Part XI: Mobility....2023

166 Mobility....2025
Mobility....2026
Intracontroller roaming....2026
Intercontroller roaming....2027
Intersubnet roaming....2029
SDA roaming....2031
Mobility groups....2033
Supported platforms....2034
Configure the mobility feature (GUI)....2038
Configure the mobility group (CLI)....2039
Configure inter-release controller mobility (GUI)....2041
Configure inter-release controller mobility (CLI)....2041
Verify mobility....2043

167 NAT Support on Mobility Groups....2049
NAT support for mobility groups....2050
Restrictions for NAT support on mobility groups....2051
Functionalities supported on mobility NAT....2051
Configure a mobility peer (CLI)....2052
Verify NAT support on mobility groups....2053

168 Static IP Client Mobility....2055
Static IP client mobility....2056
Restrictions for static IP client mobility....2056
Configure a static IP client mobility profile (GUI)....2056
Configure a static IP client mobility (CLI)....2057
Verify static IP client mobility....2058

169 Mobility Domain ID - 802.11i Roaming....2061
Mobility domain ID–802.11i roaming....2062
Verify mobility domain ID - 802.11i roaming....2063

170 802.11r Support for Flex Local Authentication....2065
802.11r support for FlexConnect local authentication....2066
802.11r support verification for flex local authentication....2066

171 Opportunistic Key Caching....2069
Opportunistic key caching....2070
Enable opportunistic key caching....2070
Enable opportunistic key caching (GUI)....2071
Verify opportunistic key caching....2071

Part XII: High Availability....2073

172 High Availability....2075
High Availability....2076
Prerequisites for High Availability....2078
High Availability restrictions....2079
Best practices for RP port configuration....2081
Configure High Availability (CLI)....2081
Disable High Availability....2083
Copy a WebAuth tar bundle to the standby controller (GUI)....2084
System and network fault handling....2085
Handling recovery mechanism....2104
Verify high availability configurations....2105
Verify AP or client SSO statistics....2105
Verify high availability....2107
ACI network controllers....2111
Configure a switchover....2115
Auto-upgrade feature....2115
Auto-upgrade use cases....2116
Configuration workflow....2116
Configure auto-upgrade (CLI)....2117
Link layer discovery protocol use cases....2117
Enable LLDP (CLI)....2118
Enable LLDP timers (CLI)....2118
Enable LLDP TLV-Select (CLI)....2119
LLDP verification....2120
Reload reason history....2122
Feature history....2123
Request reload reason history using YANG....2123
Reload reason history verification....2125

173 Redundancy Management Interface....2129
Redundancy management interfaces....2130
Gateway monitoring....2130
Gateway statistics monitoring....2132
Gateway reachability detection....2133

Standby monitoring....2135
Standby controller health monitoring using programmatic interfaces....2140
Standby controller health monitoring (CLI)....2140
Gateway-monitoring configuration verification....2143
RMI IPv4 configuration verification....2144
RMI IPv6 configuration verification....2145
Redundancy port interface configuration verification....2146
Redundancy management interfaces....2148
Controller operations with Redundant Management Interface....2151
Dual stack configurations on management vlans with RMI....2151
RMI-based high-availability pairings....2152
HA pairing without previous configuration....2153
Paired controllers....2154
Upgrade from Cisco IOS XE 16.1.x to a later release....2155
Configure redundancy management interface (GUI)....2156
Configure redundancy management interface (CLI)....2157

Part XIII: Quality of Service....2161

174 Quality of Service....2163
Wireless Quality of Service....2164
Wireless QoS targets....2164
Wireless QoS mobility....2166
Precious metal policies for wireless QoS....2166
Prerequisites for wireless QoS....2167
Restrictions for QoS on wireless targets....2167
Bidirectional rate limiting....2169
Apply metal policy with bidirectional rate limiting....2170
Requirements for bidirectional rate limiting configuration....2171
Configure the metal policy on the SSID....2171
Configure a metal policy on your client device....2172
Configure bidirectional rate limiting for all traffic....2173
Configure Bi-Directional Rate Limiting Based on Traffic Classification....2173
Apply bidirectional rate limiting policy map to policy profile....2175
Apply metal policy with bidirectional rate limiting....2176
Per-client bidirectional rate limiting....2178
Use case for per-client bidirectional rate limiting....2178
Process for per-client bidirectional rate limiting....2179
Prerequisites for per-client bidirectional rate limiting....2179
Restrictions on per-client bidirectional rate limiting....2179
Configure per-client bidirectional rate limiting (GUI)....2179
Verify per client bi-directional rate limiting....2180
Configure bi-directional rate limiting using AAA override (CLI)....2180
Verify bi-directional rate-limit....2181

How to configure wireless QoS....2183
Configure a policy map with class map (GUI)....2183
Configure a class map (CLI)....2184
Configuring Policy Profile to Apply QoS Policy (GUI)....2185
Configure policy profile to apply QoS policy (CLI)....2186
Apply policy profile to policy tag (GUI)....2187
Apply policy profile to policy tag (CLI)....2187
Attach policy tag to an AP....2188
Configure custom QoS mapping (CLI)....2189
Configure a DSCP-to-user priority mapping exception....2191
Configure trust upstream DSCP value....2192

175 Wireless Auto-QoS....2195
Auto QoS information....2196
Configure wireless auto-QoS on profile policy (CLI)....2196
Disable wireless autoqos....2197
Rollback auto-QoS configuration (GUI)....2198
Rollback AutoQoS configuration (CLI)....2198
Clear wireless autoqos policy profile (GUI)....2199
Clear wireless autoqos policy profile (CLI)....2199
View Auto-QoS on policy profile (CLI)....2200

176 Native Profiling....2203
Native profiling....2204
Create a class map (GUI)....2205
Create a class map (CLI)....2206
Create a service template (GUI)....2208
Create a service template (CLI)....2208
Create a parameter map (CLI)....2210
Create a policy map (GUI)....2210
Create a policy map (CLI)....2211
Configure native profiling in local mode (CLI)....2214
Verify native profile configuration....2214

177 Air Time Fairness....2217
Air time fairness....2218
Restrictions on Cisco air time fairness....2219
Cisco air time fairness use cases....2219
Configure Cisco air time fairness....2220
Create a Cisco ATF profile (GUI)....2220
Create Cisco ATF profile (CLI)....2221
Attach Cisco ATF profile to a policy profile (GUI)....2222
Attach Cisco ATF profile to a policy profile (CLI)....2222

Enable ATF in the RF profile (GUI)....2223
Enable ATF in the RF profile (CLI)....2224
Cisco ATF configuration verification....2225
Cisco ATF statistics verification....2225

178 IPv6 Non-AVC QoS Support....2227
IPv6 non-AVC QoS support....2228
Mark DSCP values in an IPv6 packet (CLI)....2228
Drop an IPv6 packet with DSCP values (CLI)....2229
Configure policing for IPv6 traffic (CLI)....2230
IPv6 non-AVC QoS verification....2231

179 QoS Basic Service Set Load....2233
QoS basic set service load....2234
Configure Wi-Fi multimedia (CLI)....2234
Enable QoS basic set service load (CLI)....2236
QoS basic set service load verification....2237

Part XIV: IPv6....2239

180 IPv6 Client IP Address Learning....2241
IPv6 client address learning....2242
Prerequisites for IPv6 client address learning....2242
Configure IPv6 interface on a switch (GUI)....2242
Configure IPv6 on Interface (CLI)....2243
Address assignment using SLAAC....2244
Stateful DHCPv6 address assignment....2245
Router solicitation....2251
Router advertisement....2251
Neighbor discovery....2254
Neighbor discovery suppression....2255
IPv6 address tracking for wireless clients....2255
Configure unknown address multicast neighbor solicitation forwarding (CLI)....2256
Native IPv6....2257
IPv6....2257
General guidelines and unsupported features of IPv6....2258
Configure IPv6 addressing (CLI)....2258
Create an AP join profile (GUI)....2260
Create an AP join profile (CLI)....2260
Configure the primary and backup Controller (GUI)....2261
Configure primary and backup controller (CLI)....2261
Verify IPv6 configuration....2262

181 IPv6 ACL....2263
IPv6 ACL....2264
Understand IPv6 ACLs....2264
Types of ACL....2264
Prerequisites for configuring IPv6 ACL....2265
Restrictions for configuring IPv6 ACL....2265
Configure IPv6 ACLs....2265
Default IPv6 ACL configuration....2265
Interact with other features and switches....2266
Create an IPv6 ACL (GUI)....2266
Create an IPv6 ACL (CLI)....2267
Create WLAN IPv6 ACL (GUI)....2269
Create WLAN IPv6 ACL (CLI)....2270
Verify IPv6 ACL....2270
Display IPv6 ACLs (CLI)....2271
Example: Create an IPv6 ACL....2271
Example: Apply an IPv6 ACL to a policy profile in a wireless environment....2272
Display IPv6 ACLs (CLI)....2272
Example: Display IPv6 ACLs....2273
Example: Configure RA throttling....2273

182 Configuring IPv6 Mobility....2275
IPv6 client mobility....2276
Using router advertisement....2277
Router advertisement throttling....2278
IPv6 address learning....2278
Handling multiple IP addresses....2278
IPv6 configuration....2279
Prerequisites for IPv6 client mobility....2279
Monitor IPv6 client mobility....2279

183 IPv6 Support on Flex and Mesh....2281
IPv6 support on FlexConnect + mesh deployment....2282
Configure IPv6 support for FlexConnect + Mesh (CLI)....2282
Configure preferred IP address as IPv6 (GUI)....2283
Configure preferred IP address as IPv6 (CLI)....2283
Verify IPv6 on FlexConnect + Mesh....2284

184 IPv6 CAPWAP UDP Lite Support....2287
UDP Lite....2288
Enable UDP lite support (CLI)....2288
Verify UDP lite support configuration....2289

185 Neighbor Discovery Proxy....2291
Neighbor discovery....2292
Neighbor discovery proxy....2292
Duplicate address detection proxy....2293

186 Address Resolution Protocol Proxy....2295
Address resolution protocol....2296
Address resolution protocol proxy....2296

187 IPv6 Ready Certification....2299
IPv6 ready certification....2300
Configure IPv6 route information (CLI)....2300
Verify IPv6 route information....2301

Part XV: CleanAir....2303

188 Cisco CleanAir....2305
Cisco CleanAir....2306
Cisco CleanAir-related terms....2307
Cisco CleanAir components....2307
Prerequisites for CleanAir....2308
Difference between Spectrum Intelligence and Cisco CleanAir....2309
EDRRM and AQR update mode....2311
Configure CleanAir....2311
Enable CleanAir for the 2.4-GHz band (GUI)....2311
Enable CleanAir for the 2.4-GHz band (CLI)....2312
Configure a CleanAir alarm for 2.4-GHz air-quality and devices (CLI)....2312
Configure interference reporting for a 2.4-GHz device (GUI)....2313
Configure interference reporting for a 2.4-GHz device (CLI)....2314
Enable CleanAir for the 5-GHz band (GUI)....2315
Enable CleanAir for the 5-GHz band (CLI)....2315
Configure interference reporting for a 5-GHz device (GUI)....2315
Configure interference reporting for a 5-GHz device (CLI)....2316
Configure event driven RRM for a CleanAir event (GUI)....2318
Configure EDRRM for a CleanAir event (CLI)....2318
Verify CleanAir support on connected APs....2319
CleanAir Pro scanning....2320
Configuration examples for CleanAir....2324
CleanAir Pro scanning....2324
Enable CleanAir Pro scan features (CLI)....2326
Monitor CleanAir Pro statistics (GUI)....2327

Verify CleanAir Pro scanning details....2328
Verify CleanAir parameters....2329
Configure air quality traps (CLI)....2330
Monitor with CleanAir device clusters....2330
CleanAir FAQs....2331

189 Bluetooth Low Energy....2333
Bluetooth low energy....2334
Enable Bluetooth low energy beacon (GUI)....2334
Enable Bluetooth low energy beacon (CLI)....2335

190 Persistent Device Avoidance....2337
Cisco persistent device avoidance....2338
Configure persistent device avoidance (GUI)....2338
Configure persistent device avoidance (CLI)....2339
Verify persistent device avoidance....2339

191 Spectrum Intelligence....2343
Spectrum Intelligence....2344
Configure spectrum intelligence (CLI)....2344
Verify spectrum intelligence information....2345
Debugg spectrum intelligence on supported APs (CLI)....2346

192 Spectrum Analysis....2349
Spectrum analysis....2350
Live spectrum analysis....2350
Perform AP spectrum analysis (GUI)....2350
Configure spectrum analysis (CLI)....2351
Verify spectrum analysis....2352

Part XVI: Mesh Access Points....2353

193 Mesh Access Points....2355
Mesh network....2356
Mesh RRM feature support and evolution across AP generations....2357
Restrictions for mesh access points....2357
Country codes....2358
Mesh interoperability between controllers....2358
Enable wireless mesh profile (CLI)....2359
Associate wireless mesh to an AP profile (CLI)....2360
Verify mesh configuration....2360
Mesh Authorization and Security....2369

MAC authorization....2369
EAP authentication....2372
Preshared key provisioning....2374
Provision LSC for bridge-mode and mesh APs (GUI)....2376
Provision LSC for bridge-mode and mesh APs....2377
Intrusion detection system....2378
Bridge group names....2379
Configure a bridge group name (GUI)....2380
Configure a bridge group name (CLI)....2380
Mesh background scanning....2381
Background scanning and MAP fast ancestor find mode....2382
Configure background scanning (GUI)....2382
Configure background scanning....2383
Configure AP fast ancestor find mode (GUI)....2383
Configure background scanning and MAP fast ancestor find mode (Task)....2384
Verify background scanning and MAP fast ancestor find....2385
Mesh serial backhaul....2385
Enable serial backhaul in radio profile (GUI)....2386
Enable mesh configurations in radio profile (CLI)....2387
Enable serial backhaul (CLI)....2388
Verify mesh serial backhaul....2389
Mesh backhaul RRM....2390
Radio Resource Management on mesh....2391
Configure RRM on mesh backhaul (CLI)....2392
Configure RRM channel assignment for root access points globally....2392
Configure RRM channel assignment for an AP....2393
RRM DCA status verification....2394
Dynamic frequency selection....2395
Spectrum Intelligence for mesh....2396
Mesh backhaul at 2.4 GHz and 5 GHz 2396
Configure mesh backhaul (CLI)....2397
Specify the backhaul slot for the root AP (GUI)....2397
Specify the backhaul slot for the root AP (CLI)....2398
Mesh backhaul verification....2398
Backhaul client access....2399
Configure dot11ax rates on mesh backhaul per AP (GUI)....2401
Configure Dot11ax rates on mesh backhaul in mesh profile (GUI)....2401
Configure wireless backhaul data rate (CLI)....2402
Configure data rate per AP (CLI)....2403
Configure data rate using mesh profile (CLI)....2404
Verify dot11ax rates on mesh backhaul....2405
Ethernet bridging....2405
Configure Ethernet bridging (GUI)....2406
Configure Ethernet bridging (CLI)....2406
Multicast over mesh Ethernet bridging network....2408

Configure multicast modes over mesh....2409
Workgroup bridge....2410
DHCP and NAT functionality on root AP (RAP)....2410
How DHCP and NAT functionalities work on root AP - IPv4 scenario....2411
Configure DHCP server on root AP (CLI)....2411
DHCP server for root AP configuration verification....2412
Mesh convergence....2412
Noise-tolerant fast detection....2413
Configure mesh convergence (CLI)....2413
Mesh convergence verification....2414
Mesh network recovery mechanisms....2414
Mesh daisy chaining....2415
Prerequisites for mesh Ethernet daisy chaining....2415
Restrictions for mesh Ethernet daisy chaining....2415
Configure mesh Ethernet daisy chaining (CLI)....2416
Enable mesh Ethernet daisy chaining....2416
Mesh Ethernet daisy chaining verification....2417
FlexConnect + bridge mode....2417
Flex resilient with Flex and bridge modes....2418
Mesh AP Roles and Topology....2425
Select a preferred parent (GUI)....2426
Select a preferred parent (CLI)....2426
Change the role of an AP (GUI)....2427
Change the role of an AP (CLI)....2427
Mesh leaf node....2428
Configure subset channel synchronization....2429
Configure battery state for mesh AP (GUI)....2430
Configure battery state for mesh AP (CLI)....2430
Link test....2431
Use a link test on mesh backhaul (GUI)....2431
Use a link test on mesh backhaul....2432
Air time fairness on mesh....2433
Configure ATF on mesh (GUI)....2434
Configure ATF on mesh....2434
Create an ATF policy for a MAP....2435
Create an ATF policy (GUI)....2435
Add an ATF to a policy profile (GUI)....2436
Enable ATF mode in an RF profile (GUI)....2436
Verify ATF configuration on mesh....2437
Mesh call admission control....2438
Configure mesh CAC (CLI)....2438
Fast teardown for a mesh deployment....2439
Configure fast teardown for a mesh AP profile (GUI)....2439
Configure fast teardown for a mesh AP profile (CLI)....2440
Fast teardown verification with default mesh profile....2441

194 Redundant Root Access Point (RAP) Ethernet Daisy Chaining.....2443
Redundant RAP Ethernet daisy chaining.....2444
Prerequisites for redundant RAP Ethernet daisy chaining support.....2444
Configure redundant RAP Ethernet daisy chaining support (CLI).....2444
Verify daisy chain redundancy.....2445

Part XVII: URWB.....2447

195 URWB.....2449
Ultra-Reliable Wireless Backhaul Background.....2450
Topologies.....2450
Benefits.....2450
Limitations and restrictions.....2451
Configure URWB using the controller.....2451
Create URWB network profile (GUI).....2451
Configure URWB network profile (CLI).....2453
Limitations and guidelines for secondary Ethernet ports 2460
Configure secondary Ethernet port (GUI) 2461
Configure secondary Ethernet port (CLI).....2462
Create URWB radio profile (GUI).....2463
Create URWB radio profile (CLI).....2465
Configure URWB parameters in the privileged EXEC mode.....2471
Verify URWB details.....2473
URWB telemetry protocol.....2474
Configure URWB telemetry protocol using AP CLI.....2474
Monitor URWB network information using Controller (GUI).....2476
Verify AP URWB information 2477
URWB recovery 2478
Prerequisites.....2478
Configure the URWB recovery using AP CLI.....2478
Country code behavior on AP models.....2480
URWB recovery configuration example.....2481
Dynamically configure URWB parameters.....2482
Hot-configurable URWB parameters.....2482
Parameters requiring a device reload.....2483
Configure URWB parameters using CLI.....2483
Configure URWB parameters using GUI.....2484
View configuration update summary.....2485
Controller-directed URWB traffic.....2485
URWB clients.....2485
URWB traffic egress point.....2486
URWB client WLANs.....2486

URWB mobility across subnets....2486
Limitations of Controller-directed URWB traffic....2487
How URWB client mobility works....2487
Create VLAN for vehicle AP and wired client (GUI)....2487
Create VLAN for vehicle AP and wired client....2488
Create URWB profile for mobility role base and client (GUI)....2489
Create URWB profile for mobility role base and client....2491
Create policy tag profile (GUI)....2493
Create policy tag profile....2494
Bind policy tag to coordinator APs (GUI)....2495
Bind the policy tag to coordinator APs....2495
Configure VLAN tagging for vehicle AP (GUI)....2496
Configure VLAN tagging for the vehicle AP....2497
View the client type information....2497
Support for 6 GHz Low Power Indoor mode....2498
Restrictions....2499
How 6 GHz mobility clients operate....2499
Configure the 6-GHz LPI mode....2500
Verify 6 GHz Low Power Indoor on AP in mobility client role....2505
NAT/PAT for URWB....2506
Guidelines for NAT/PAT configuration....2507
Configure NAT/PAT for URWB (GUI)....2507
Configure NAT/PAT for URWB....2508

Enable ARP broadcast on VLAN (GUI)....2573
Enable ARP broadcast on VLAN (CLI)....2574
Passive client in fabric deployment....2575
Enable broadcast underlay on VLAN....2575
Enable ARP flooding....2577
Verify passive client configuration....2580

199 Fabric in a Box with External Fabric Edge....2583
Fabric in a Box with external Fabric Edge....2584
Configure a Fabric profile (CLI)....2584
Configure a policy profile (CLI)....2585
Configure a site tag (CLI)....2586

Configure a WLAN (CLI)....2587
Configure a policy tag (CLI)....2587
Configure an AP profile (CLI)....2588
Configure map server and AP subnet (CLI)....2589
Configure Fabric on FiaB node (CLI)....2590
Configure a Fabric Edge Node (CLI)....2594
Verify Fabric configuration....2599

Part XX: VLAN....2605

200 VLANs....2607
Virtual Local Area Network....2608
Supported VLANs....2608
VLAN port membership modes....2608
VLAN configuration files....2609
Normal-range VLAN configuration guidelines....2610
Extended-range VLAN configuration guidelines....2610
Prerequisites for VLANs....2610
Restrictions for VLANs....2611
Configuring normal-range VLANs....2612
Create or modify an Ethernet VLAN (CLI)....2612
Assign static-access ports to a VLAN (GUI)....2613
Assign static-access ports to a VLAN (CLI)....2613
Extended-range VLANs....2614
Create an extended-range VLAN (GUI)....2615
Create an extended-range VLAN (CLI)....2615
Monitor VLANs....2616

201 VLAN Groups....2617
VLAN groups....2618
Prerequisites for VLAN groups....2618
Restrictions for VLAN groups....2618
Create a VLAN Group (GUI)....2619
Create a VLAN Group (CLI)....2619
Add a VLAN group to policy profile (GUI)....2620
Add a VLAN group to a policy profile (CLI)....2620
View the VLANs in a VLAN group....2621
VLAN group support for DHCP and static IP clients....2621
Prerequisites and restrictions of VLAN Group support for DHCP and static IP clients....2622
Supported features....2622

Part XXI: WLAN....2625

202 WLANs.....2627
WLANs.....2628
Prerequisites for WLANs.....2629
Restrictions for WLANs.....2629
Band selection.....2630
Off-channel scanning deferral.....2630
DTIM period.....2631
WLAN radio policies.....2632
Restrictions for WLAN radio policy.....2632
Prerequisites for configuring Cisco client extensions.....2632
Peer-to-peer blocking.....2633
Diagnostic channels.....2633
AP names in beacon.....2633
How to configure WLANs.....2634
WLAN wizard.....2634
Create WLANs (GUI).....2646
Create WLANs (CLI).....2647
Delete WLANs (GUI).....2648
Delete WLANs (CLI).....2648
WLAN search methods (CLI).....2649
Enable WLANs (GUI).....2650
Enable WLANs (CLI).....2650
Disable WLANs (GUI).....2651
Disable WLANs (CLI).....2651
Configure general WLAN properties (CLI).....2652
Configure advanced WLAN properties (CLI).....2654
Configure advanced WLAN properties (GUI).....2656
Configure WLAN radio policy (GUI).....2658
Configure a WLAN radio policy (CLI).....2659
Configure AP name advertisement in beacons (GUI).....2661
Configure AP name advertisement in beacons.....2661
WLAN properties verification (CLI).....2662
Verify WLAN-VLAN information of an AP.....2663
WLAN radio policy verification.....2663
Verify AP name advertisement.....2664

203 WLAN Security.....2665
WPA1 and WPA2 security protocols.....2666
Restrictions for WPA2 and WPA3.....2667
Prerequisites for Layer 2 Security.....2667
AAA override.....2667
Configure AAA override (CLI).....2667
VLAN override.....2668

Configure override VLAN for central switching (CLI)....2669
Configure override VLAN for local switching (CLI)....2670
VLAN override on Layer 3 web authentication....2671
VLAN override verification on Layer 3 web authentication....2672
Fallback for AAA-overridden VLAN....2672
Feature history for fallback for AAA-overridden VLAN....2672
Central switching and FlexConnect mode scenarios....2673
Configure fallback for AAA-overridden VLAN (CLI)....2674
Verify fallback for AAA-overridden VLAN....2675
How to configure WLAN security....2675
Configure static WEP Layer 2 security parameters (GUI)....2675
Configure static WEP layer 2 security parameters (CLI)....2676
Configure WPA + WPA2 Layer 2 security parameters (GUI)....2678
Configure WPA + WPA2 layer 2 security parameters (CLI)....2678

204 Remote LANs....2683
Remote LANs....2684
Limitations of RLAN....2685
Configure remote LANs (RLANs)....2686
RLAN authentication fallback....2702
Configure RLAN authentication fallback (CLI)....2703
Modify 802.1X EAP timers for RLAN clients....2704
Verify RLAN authentication fallback....2705

205 RLAN External Module....2707
External module....2708
Requirement: Prerequisites for configuring external module....2708
Configure external module (GUI)....2708
Configure external module (CLI)....2708
External module verification....2709

206 802.11ax Per WLAN....2711
802.11ax mode per WLAN....2712
Configure 802.11ax mode per WLAN (GUI)....2712
Configure 802.11ax mode per WLAN (CLI)....2713
Verify 802.11ax mode per WLAN....2713

207 BSS Coloring....2715
BSS coloring....2716
BSS coloring....2716
OBSS-PD and spatial reuse....2717
Configure BSS color on AP (GUI)....2717
Configure BSS color in the privileged EXEC mode....2717

Configure BSS color globally....2718
Configure BSS color in the configuration mode....2718
Configure overlapping BSS packet detect (GUI)....2719
Configure OBSS-PD spatial reuse globally (CLI)....2719
Configure OBSS PD in an RF profile (GUI)....2720
Configure OBSS-PD spatial reuse in the RF profile mode (CLI)....2721
BSS color and OBSS-PD verification....2722

208 DHCP for WLANs....2725
Dynamic Host Configuration Protocol....2726
Internal DHCP servers....2726
External DHCP servers....2727
DHCP assignments....2727
DHCP option 82....2728
Restrictions for configuring DHCP for WLANs....2729
Guidelines for DHCP relay configuration....2729
Configure DHCP for WLANs....2730
Configure DHCP scopes (GUI)....2730
Configure DHCP scopes (CLI)....2731
Configure internal DHCP server....2732
Configure the internal DHCP server under client VLAN SVI (GUI)....2732
Configure the internal DHCP server under client VLAN SVI (CLI)....2733
Configure the internal DHCP server under a wireless policy profile (GUI)....2737
Configure the internal DHCP server under a wireless policy profile (CLI)....2738
Configure the internal DHCP server globally (GUI)....2742
Configure the internal DHCP server globally (CLI)....2742
Configure IP reservations in the internal DHCP server (CLI)....2746
Verify internal DHCP configuration....2747
Configure DHCP-Required for FlexConnect....2749
FlexConnect DHCP-Required....2749
Restrictions for FlexConnect DHCP-Required....2749
Configure FlexConnect DHCP-Required (GUI)....2750
Configure FlexConnect DHCP-required (CLI)....2751
Verify FlexConnect DHCP-required....2752

209 Aironet Extensions IE (CCX IE) 2753
Cisco Aironet Extensions Information Element....2754
Configure Aironet Extensions IE using GUI....2754
Configure Aironet Extensions IE (CLI)....2754
AP name addition verification....2755

210 Device Analytics....2757
Device analytics....2758

Restrictions for device analytics....2758
Configure device analytics (GUI)....2758
Configure device analytics (CLI)....2759
Verify device analytics....2761
Verify device analytics configuration....2761
Adaptive 802.11r....2763
Configure adaptive 802.11r (GUI)....2764
Adaptive 802.11r verification....2764

211 Device Classifier Dynamic XML Support....2767
Device classifier dynamic XML support....2768
Feature history for device classifier dynamic XML support....2771
Enable device classifier (CLI)....2772
Update dynamic XML file....2773
Verify TLV value....2774
Old classification cache clearing....2774

212 BSSID Counters....2777
BSSID counters....2778
Enable BSSID statistics and BSSID neighbor statistics (CLI)....2778
BSSID statistics verification on the controller....2779

213 Fastlane+....2783
Fastlane+....2784
Configure Fastlane+ on a WLAN (CLI)....2784
Configure Fastlane+ on a WLAN (GUI)....2785
Monitor Fastlane+ (GUI)....2785
Fastlane+ verification....2786

214 Workgroup Bridges....2789
Cisco Workgroup Bridges....2790
Restrictions for WGB....2792
Configure a WGB on a WLAN (CLI)....2793
Verify WGB status on the controller....2795
Configure AP as WGB....2795
Configure Cisco Wave 2 APs or 11AX APs in WGB or CAPWAP AP mode (CLI)....2795
Configure an SSID profile for Cisco Wave 2 and 11AX APs (CLI)....2796
Configure the authentication server (CLI)....2798
Configure dot1X credential (CLI)....2799
Configure an EAP profile (CLI)....2800
Configure manual-enrollment of a Trustpoint for WGB (CLI)....2801
Configure auto-enrollment of a Trustpoint for workgroup bridge (CLI)....2803
Configure manual certificate enrollment using TFTP server (CLI)....2805

Import the PKCS12 format certificates from the TFTP server (CLI)....2807
Configure radio interface for workgroup bridges (CLI)....2807
Configure workgroup bridge timeouts (CLI)....2811
Configure bridge forwarding for workgroup bridge (CLI)....2813
Simplified WGB configuration....2814
Configure multiple WGBs (CLI)....2815
Verify WGB configuration....2816

215 Peer-to-Peer Client Support....2819
Peer-to-peer client support....2820
Configure peer-to-peer client support....2820

216 Deny Wireless Client Session Establishment Using Calendar Profiles....2823
Denial of wireless client session establishment....2824
Guidelines and limitations....2825
Configure daily calendar profile (CLI)....2825
Configure weekly calendar profile (CLI)....2826
Configure monthly calendar profile (CLI)....2828
Map daily calendar profile to policy profile (CLI)....2829
Map weekly calendar profile to policy profile (CLI)....2831
Map monthly calendar profile to policy profile (CLI)....2832
Verify calendar profile configuration....2834
Verify policy profile configuration....2834

217 Ethernet over GRE....2837
Ethernet over GRE....2838
EoGRE configuration....2839
Create a tunnel gateway (CLI)....2840
Configure the tunnel gateway (GUI)....2841
Configure a tunnel domain (CLI)....2841
Configure tunnel domain (GUI)....2842
Configure EoGRE global parameters CLI)....2843
Configure EoGRE global parameters (GUI)....2844
Configure a tunnel profile (CLI)....2845
Configure the tunnel profile (GUI)....2847
Associate WLAN to a wireless policy profile (CLI)....2848
Attach a policy tag and a site tag to an AP....2849
Verify EoGRE tunnel configuration....2850

Cisco 9800 Series Wireless Controllers

Introduces the Cisco Catalyst 9800 Series Wireless Controller, describing its architecture, key functionalities, and core benefits for next-generation wireless networks.

Cisco Catalyst 9800 Series Wireless Controllers are the next generation wireless controllers that

- are IOS XE based and integrate the Radio Frequency (RF) performance excellence from Aironet systems,
- supports intent-based networking that are easy to adapt and scale, and
- are available in multiple physical and virtual form factors for flexible management options.

Available form factors and deployment options

You can deploy the controllers as physical appliances or as virtual devices in private and public cloud environments.

The controllers cater to these deployment options:

- Cisco Catalyst 9800 Series Wireless Controller Appliance
- Cisco Catalyst 9800 Series Wireless Controller for Cloud
- Cisco Catalyst 9800 Embedded Wireless for Switch

Management options

You can managed them the Cisco Catalyst 9800 Series Wireless Controllers with:

- Cisco Catalyst Center
- NETCONF or YANG, or
- GUI or CLI.

Cisco Prime Infrastructure is also supported.

Configuration data model

Explains the configuration data model structure for the controller, detailing how configuration information is organized, managed, and implemented within the system.

A configuration data model is a framework that

- enables reusability of network settings and components
- supports simplified provisioning for scalable network management, and
- provides enhanced flexibility and modularization to adapt to changing business and IT requirements.

For more information, see Information About New Configuration Model.

Initial controller setup methods

Outlines methods for initial setup of the Cisco Catalyst 9800 Series Wireless Controller using both GUI and CLI, and provides instructions for deploying controllers in environments of various sizes to support AP connectivity and wireless services.

The initial configuration wizard in Cisco Catalyst 9800 Series Wireless Controller is a simplified, out-of-the-box installation and configuration interface for the controller. This section provides instructions to set up a controller to operate in a small, medium, or large network wireless environment, where access points can join and together as a simple solution provide various services, such as corporate employee or guest wireless access on the network.

Setting up the controller using GUI

To set up the controller using the GUI, see the `Configuring Wireless Controller section` in Cisco Catalyst 9800 Wireless Controller Series Web UI Deployment Guide.

Setting up the controller using CLI

To set up the controller using CLIs, see the `Performing the Initial Configuration on the Controller` section of your respective controller installation guides.

- Cisco Catalyst 9800-80 Wireless Controller Hardware Installation Guide
- Cisco Catalyst 9800-40 Wireless Controller Hardware Installation Guide
- Cisco Catalyst 9800-L Wireless Controller Hardware Installation Guide
- Cisco Catalyst 9800-CL Cloud Wireless Controller Installation Guide
- Cisco Catalyst CW9800M Wireless Controller Hardware Installation Guide
- Cisco Catalyst CW9800H1 and CW9800H2 Wireless Controllers Hardware Installation Guide

Restrictions for initial controller setup

Network Reset Commands for EWC Devices

Do not use the **erase startup-config** command if you intend to reset EWC, APs, and EWC-APs in the network to Day0 state. We recommend that you use the **wireless ewc-ap factory-reset** command.

This restriction applies when resetting an EWC device and all associated APs and EWC-APs in a wireless network to their factory default (Day0) state.

The **erase startup-config** command only removes the configuration from the local device and does not synchronize the reset across other devices in the network. In contrast, the **wireless ewc-ap factory-reset** command resets the EWC device and all connected APs and EWC-APs to Day0 state, ensuring network-wide consistency.

Setting up the controller Using GUI

- To identify remote users in the GUI, the remote authentication server (RADIUS or TACACS) must send the user-type attribute with value 6.
- If you make configuration changes in the CLI and in the GUI simultaneously, you must click the **Refresh** button in the GUI to synch both the changes. You should always click the **Refresh** button in the GUI to update the changes done through the CLI.
- When you go to the login page, the controller sends a request to the RADIUS server for the banner text. You can view this request on the RADIUS server.
- When you log in to the Cisco Catalyst 9800-L Wireless Controller GUI, you receive many CPU alerts because of the CPU utilization spikes during log in.
- Header size refers to the cookies sent from the browser through the controller GUI to the device WebSocket server in a WebSocket header. If the size of the cookie exceeds 4 KB, then any request that is made to the WebSocket server (query or configuration) via the GUI would fail. In such a case, ensure that you clear the browser cookies and cache, periodically.

  The banner text displayed on the browser is fetched from the controller. You can view this request on the RADIUS server.

Synchronize changes across CLI and GUI using Refresh

- If you make configuration changes in the CLI and in the GUI simultaneously, you must click the **Refresh** button in the GUI to synchronize the changes.

Interactive help

Details the interactive help features, guiding users through supported workflows and providing contextual assistance for configuring and managing the controller.

Interactive help is a user interface feature that

- provides step-by-step guidance within the application
- adapts instructions and walk-throughs to the user's context, and
- assists users in completing complex configurations or navigating the system.

Modes of starting the interactive Help

You can start the interactive help in the these ways.

- Hover over the blue flap at the right-hand corner of a window in the GUI and clicking **Interactive Help**.
- Click **Walk-me Thru** in the left pane of a window in the GUI.
- Click **Show me How** whenever displayed in the GUI. Clicking **Show me How** triggers a specific interactive help that is relevant to the context you are in.

  For example, **Show me How** in **Configure** > **AAA** walks you through the various steps for configuring a RADIUS server. Choose **Configuration> Wireless Setup** > **Advanced** and click **Show me How** to trigger the interactive help that walks you through the steps relating to various kinds of authentication.

Additional troubleshooting information

If the WalkMe launcher is unavailable on Safari, modify the browser settings.

1. Choose **Preferences** > **Privacy**.
2. In the **Website tracking** section, uncheck the **Prevent cross-site tracking** check box to disable this action.
3. In the **Cookies and website data** section, uncheck the **Block all cookies** check box to disable this action.

Cisco Support Assistant

Introduces the Cisco Support Assistant, explaining its integrated support capabilities and how it assists with troubleshooting, diagnostics, and streamlining case resolution.

Cisco Support Assistant (CSA) is an in-product support tool that

- provides built-in integration of Cisco Support Assistant Extension (CSAE) into the controller GUI without the need for installation of a Chrome browser extension (CSA Embed)
- integrates Cisco Technical Assistance Center (TAC) support functions directly into the GUI, and
- enables easy and quick access to Cisco support without leaving the GUI.

CSA Embed is the built-in integration of the Cisco Support Assistant Extension (CSAE) within the controller, that does not require installation of the Chrome browser extension.

Feature History

Feature Name	Release	Description
Cisco support assistant integration to WLC GUI	Cisco IOS XE 17.18.2	This feature integrates the Cisco Support Assistant (CSA) directly within the controller GUI. You can now open TAC cases, upload logs, record screens, and access contextual help directly from within the controller interface, and without installing the Chrome browser extension. You can find a feature demonstration here.

Supported features

1. **Case Open**: Provides an intuitive, context-aware interface for customers to open TAC cases directly from the GUI. You can attach relevant logs and files easily, ensuring faster case resolution with minimal manual steps.
2. **Screen Recording**: Allows your to record on-screen activities to demonstrate issues visually during case submission. These recordings help TAC engineers quickly understand the problem context, leading to more efficient troubleshooting.
3. **File Upload**: Simplifies the process of uploading diagnostic files and configuration logs to Cisco TAC. Secure file transfer is integrated directly within the GUI. This makes it easy to share your files while maintaining compliance and privacy standards.
4. **Smart Tooltips**: Provides contextual guidance throughout the GUI by displaying helpful hints, quick links to Cisco documentation, and troubleshooting insights. This increases your self-service capabilities and reduces your need to contact support.
5. **Wireless Compatibility Assistant**: Integrates the wireless compatibility assistant to the **Access Point Monitoring and Configuration** controller GUI window to enable self-service for wireless configuration, compatibility, best practices, and feature-related questions.

For a demonstration of the supported features, see here.

> **Note**
>
> Use CSA Embed in English for the best experience. Some CSA features may not work properly in local languages or on certain pages.

Enable CSA Embed

You can enable or disable the **CSA Embed** feature from the settings menu (**gear icon**) on the top right corner of the GUI by toggling the **Cisco Support Assistant** option.

Product analytics

Describes the product analytic capabilities, highlighting features that monitor controller operations, analyze performance trends, and support data-driven wireless network management.

Product analytics is a network device function that

- collects non-personal usage data from Cisco devices

- enables ongoing improvement of Cisco products and customer experience by analyzing that data, and
- can be configured or disabled by administrators using specific device commands.

Supported platforms

This feature is supported on the Cisco Catalyst 9800 Series Wireless Controllers (9800-80, 9800-40, 9800-L, 9800-CL, CW9800M, and CW9800H1/H2).

Management commands

You can use the the **pae** command to enable or disable this feature.To modify your organization's preferences for device and licensing systems information, use the **pae** command.

The commands are introduced as part of this feature.

- **pae**
- **show product-analytics kpi**
- **show product-analytics report**
- **show product-analytics stats**

For more information:

- Cisco Catalyst 9800 Series Wireless Controller Command Reference
- Wireless Product Analytics FAQ

Network connectivity requirements

When Product Analytics is enabled, the controller may send DNS queries to these public DNS resolver addresses, even if DNS servers are configured on the controller.

- IPv4: 208.67.222.222, 208.67.220.220, 8.8.8.8, 8.8.4.4
- IPv6: 2620:119:35::35, 2620:119:53::53, 2001:4860:4860::8888, 2001:4860:4860::8844

Privacy and data handling

Cisco collects device and licensing systems information through Cisco Smart Software Manager (CSSM) and other channels for these purposes.

- Analytics and reporting
- Product improvement
- Enhancing the customer experience

Cisco processes this data in accordance with

- Cisco Privacy Statement
- General Terms and Conditions, and
- any other applicable agreements with Cisco.

Note

Turning off Smart Licensing Device Systems Information does not impact other Systems Information collection including from Cisco Catalyst Center or vManage.

Part I

System Configuration

Topics:

- New Configuration Model
- Wireless Management Interface
- Configure Network Address Translation for Wireless Management IP
- Hardware Features
- Smart Licensing Using Policy
- Management over Wireless
- Boot Integrity Visibility
- SUDI99 Certificate Support
- Link Aggregation Group
- Reload Reason History

System Configuration

2 New Configuration Model

Topics:

- New configuration model, tags, and profile
- Tags and their associated profiles
- Configure a wireless profile policy (GUI)
- Configure a site tag (GUI)
- Enhanced site tag-based load balancing
- Wireless radio profiles
- AP filters
- Location configuration

Introduces the tag-based configuration model for wireless networks and guides through creating and associating various profile types including wireless, flex, access point, and radio frequency profiles with network infrastructure.

New configuration model, tags, and profile

Introduces the foundational elements of the tag-based configuration model and outlines the complete configuration workflow for implementing wireless network infrastructure.

The new configuration model is a wireless network configuration approach that

- uses profiles to define feature-specific parameters
- uses tags to bundle and apply profiles to APs, and
- separates policy, site, RF, and WLAN definitions for modular deployment.

Profiles define attributes such as WLAN policy, RF behavior, and AP join characteristics. Tags are logical containers that map these profiles to APs, ensuring flexible and scalable configurations.

A tag is a logical container that

- is defined by the property of policies you associate with it
- maps multiple profiles—policy, site, and RF—to an AP or client, and determines that device's configuration and behavior, and
- enables modular and flexible deployment across sites.

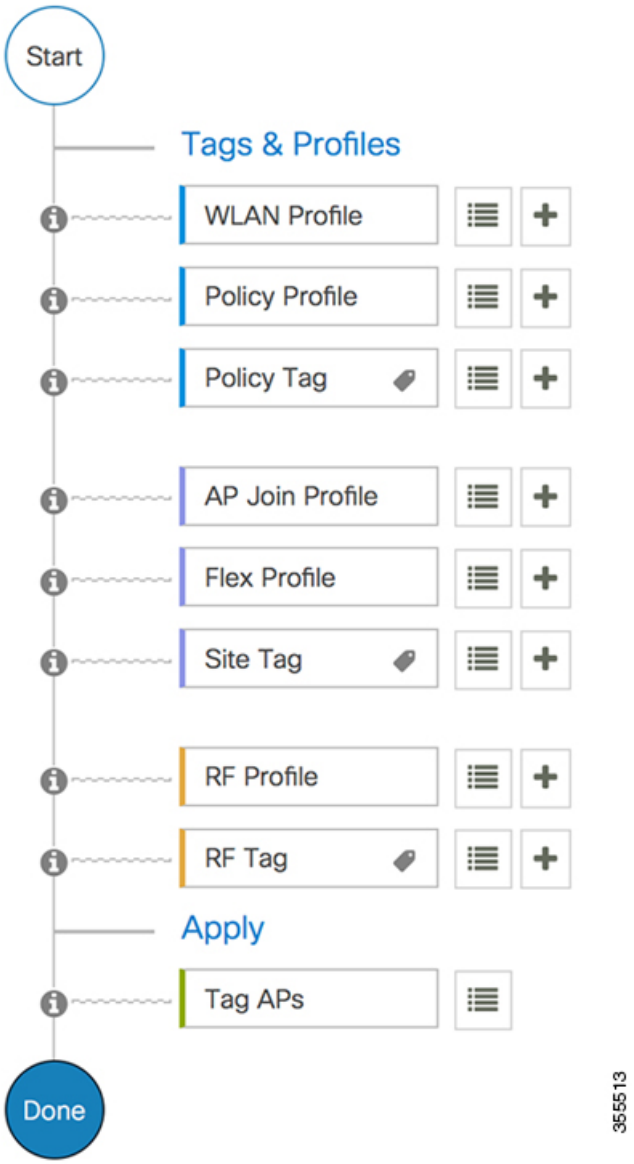
Every tag has a default that is created when the system boots up.

A profile is a logical container that

- include feature-specific attributes and parameters applied to tags
- represent multiple attributes related to policy, site, and RF
- determine the configuration and behavior of applied APs and associated clients, and
- is a reusable entities that can be used across tags.

Configuration workflow

Configuring wireless networks involves establishing profiles and tags that link configurations to APs for effective wireless management.



Summary

The key components involved in the process are:

- **Profiles**: Logical groupings of settings (such as WLAN, Policy, AP Join, Flex, and RF) used to configure APs.
- **Tags**: Logical containers or labels (such as Policy, Site, Tag) that help link profiles with APs.
- **APs**: Devices that implement the configurations provided by profiles and tags to deliver wireless connectivity.

Workflow

Figure 1: Configuration workflow

These are the stages of configuration:

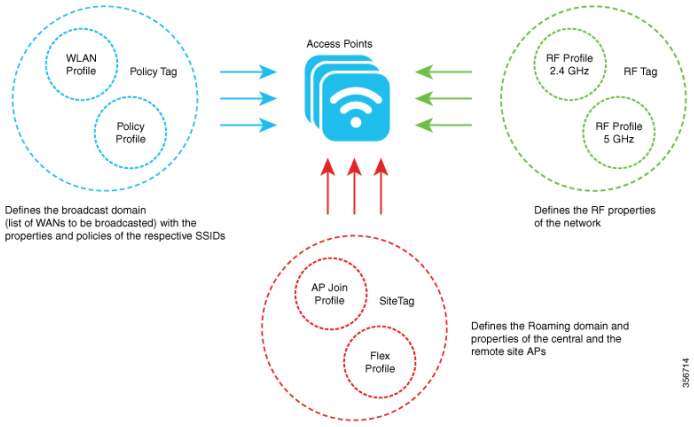
1. **Profile creation** creates specific profiles:
   - WLAN profile for managing wireless network settings.
   - Policy profile for enforcing network rules.
   - AP Join profile for controlling AP associations.
   - Flex profile for handling local switching.
   - RF profile for optimizing radio frequency settings.
2. **Tag creation**: generates tags to complement profiles:
   - Policy tag to align with the Policy profile.
   - Site tag for specific location identification.
   - RF tag corresponding to the RF profile.

3. **Tag association**: associates the created tags with an AP to apply the configured settings and policies.

Result

The configuration workflow enables APs to be set up correctly with designated profiles and tags, resulting in efficient network operation and management.

Tags and their associated profiles



Details RF tags, RF profiles, site tags, flex profiles, AP join profiles, policy tags, WLAN profiles, policy profiles, and methods for associating APs with tags.

The new configuration model has different types of tags that contain various types of profiles, depending on the functionality they represent.

Table 1: Various types of tags and the contained profiles

Tag	Contains	Function
RF Tag	Radio profile	RF tags are used to group and manage radio frequency profiles for wireless networks.
Site Tag	Flex profile and AP join profile	Site tags define the properties of a site and maps the flex profile to the the AP join profile.
Policy Tag	WLAN profile and policy profile	Policy tags map WLAN profile to the policy profile

The figure depicts the various types of tags and their contained profiles. The figure also depicts how the tag is thus applied to access points easily.

RF Tags

RF Tag fundamentals and configuration, detailing their role in wireless settings and capabilities for network optimization.

An RF tag is a configuration object that

- contains profiles for different radio frequency bands
- are used to group and manage radio frequency profiles for wireless networks

- defines global or band-specific parameters for wireless devices, and
- provides default settings for each RF profile to ensure consistent operation across radios.

The RF tag contains the 2.4 GHz, 5 GHz, and 6 GHz RF profiles. The default RF tag contains the global configuration for 2.4 and 5 GHz bands and default RF profile for 6 GHz band. All these profiles contain the same default values for global or RF profile parameters for the respective radios.

Example of RF tag

For a device operating in multiple frequency bands, applying an RF tag ensures that each radio (such as 2.4 GHz or 5 GHz) uses the network-approved configuration for coverage, performance, and reliability.

RF Profiles

Introduces RF Profiles, highlighting their significance in managing radio parameters and optimizing wireless network performance.

An RF profile is a configuration set that

- centralizes radio settings for APs
- applies a uniform set of radio parameters to all APs within an AP group, and
- ensures consistent wireless performance and feature deployment across the group.

Some RF profile options are specific to the 6-GHz band and include features such as Unsolicited Broadcast Probe Response, FILS Discovery, Multi-BSSID, and Preferred Scanning Channels. These features address 802.11ax requirements and help optimize management traffic or channel selection for reliable wireless performance..

Preferred Scanning Channels is a feature that helps RRM choose PSC channels to 6-GHz radios.

Site Tags

Describes Site Tags and their application in logically grouping access points for streamlined wireless management and policy enforcement.

A site tag is a configuration object that

- defines the properties of a wireless site
- maps a flex profile to an AP join profile, and
- specifies site-specific settings, such as a list of primary APs for upgrades.

Additional reference information

- Attributes unique to a flex or remote site are part of the flex profile, while attributes that belong to the actual physical site—like the primary APs list—are directly included in the site tag.
- The site tag includes settings that are not suited for shared, reusable profiles.
- If the flex profile name or AP profile name is changed within the site tag, associated APs are required to rejoin the controller by disconnecting their Datagram Transport Layer Security (DTLS) session.
- When a site tag is created, the AP and flex profiles default to preset values (default-ap-profile and default-flex-profile).

Example of site tag

Assigning a set of primary APs for efficient software upgrades is done through the site tag, not the flex profile, since this information applies specifically to the physical site.

Flex profiles

A Flex profile is a configuration profile that

- contains policy attributes for network management
- specifies remote site-specific parameters, and
- supports custom mappings such as VLAN-to-ACL and VLAN name-to-ID assignments.

The FlexConnect configuration helps the central controller to manage sites that are geo-distributed, for example, retail, campus, and so on.

Example of flex profile

A Flex profile can include EAP profiles used when an AP acts as an authentication server for local RADIUS information, as well as mappings for VLANs and associated ACLs or VLAN names and IDs

Analogy: A Flex profile is like a master checklist for a remote office: just as a checklist ensures every necessary step, tool, and contact is available for smooth operation at the branch, a Flex profile gathers all the required policies and site-specific settings so each access point at a remote site works according to the organization's requirements without repeated manual configuration.

AP join profiles

An AP join profile is a configuration set that

- specifies global and AP group-specific parameters for APs
- defines network and communication settings specific to an AP, such as CAPWAP, IPv4, IPv6, and protocol configurations, and
- centralizes control of AP-specfic settings—including retransmit configuration, UDP Lite, high availability, Global AP failover, Hyperlocation config parameters, Telnet and SSH, and 11u parameters—to streamline access point management across a network.

Policy Tag

A policy tag is a network configuration object that

- maps each WLAN profile to a specific policy profile
- determines how network and switching policies are assigned to wireless clients, and
- controls the deployment of WLAN and policy profiles to access points (APs) based on their enabled state.

Policy tag mapping

A policy tag maps the WLAN profile to the policy profile.

Network Configuration Object	Function
WLAN profile	defines the wireless characteristics of the WLAN.
Policy profile	defines the network policies and the switching policies for the client (Quality of Service [QoS] is an exception, which constitutes AP policies as well).

Network Configuration Object	Function
Policy Tag	maps the WLAN profile to the policy profile. There are 16 such WLAN-to-policy profile pairs. The policy tag directs how wireless services and policies are applied across the network.

Note

Quality of Service (QoS) policies are an exception, as they are managed as part of AP policies instead of policy profiles.

Example of policy tag

If a policy tag includes WLAN1 mapped to Policy1, and both profiles are enabled, their definitions are pushed to APs assigned that policy tag. If either the WLAN profile or the policy profile is disabled, that mapping is not pushed to the AP. You can also remove a WLAN profile from an AP by deleting its mapping in the policy tag configuration.

WLAN profiles

A WLAN profile is a configuration entity that

- defines the wireless network by specifying the service set identifier (SSID)
- associates Layer 2 security policies with WLANs, and
- groups related settings required for controllers to manage wireless local area networks.

Create WLANs with the same SSID you to assign different Layer 2 security policies within a single wireless LAN.

Distinguish WLANs that use the same SSID by assigning a unique WLAN profile name to each. Each WLAN with a shared SSID must have a unique Layer 2 security policy so that clients can select the appropriate WLAN based on the security information advertised in beacon and probe responses.

Note

Switching and network policies are not included in the WLAN profile definition; they are configured separately.

Analogy: A WLAN profile is like a membership card for a club. The card (profile) shows which club you belong to (SSID), lists the rules you must follow to enter (Layer 2 security policies), and includes the necessary information for the club staff (controller) to manage your membership. Just as two people can have cards for the same club but with different access levels, multiple WLAN profiles can share the same SSID but have different security policies to distinguish them.

Policy profiles

A policy profile is a network configuration entity that

- allows you to group and manage multiple policies
- is reusable across tags and deployments, and applied to APs or controllers for client access, and

- improves consistency and efficiency in large-scale wireless environments.

Example of policy profile

Policy profile centralizes policy parameters such as VLAN, access control list (ACL), Quality of Service (QoS), session timeout, idle timeout, AVC profile, Bonjour profile, local profiling, device classification, and BSSID QoS.

Table 2: Comparison between policy profiles and WLAN profiles

Policy profiles	WLAN profiles
Contain network and switching policies	Contain wireless-related security attributes, and features such as authentication and encryption
Reusable across tags and deployments, and applied to APs or controllers for client access	Configured per WLAN (SSID)

Table 3: Comparison between policy profiles and WLAN profiles

Policy profiles	WLAN profiles
Contain network and switching policies	Contain wireless-related security attributes, and features such as authentication and encryption
Reusable across tags and deployments, and applied to APs or controllers for client access	Configured per WLAN (SSID)

Analogy: A policy profile is like a preset rulebook for network access, grouping the common rules that apply to all players (clients), while the WLAN profile acts like a gatekeeper, focusing on who can enter and under what security conditions.

Table 4: Comparison between policy profiles and WLAN profiles

Policy profiles	WLAN profiles
Contain network and switching policies	Contain wireless-related security attributes, and features such as authentication and encryption
Reusable across tags and deployments, and applied to APs or controllers for client access	Configured per WLAN (SSID)

Methods for associating APs with tags

APs can be associated with tags in several ways, supporting flexible and scalable network configuration. The main association methods are:

- **Ethernet MAC address association**: The default option where an AP's Ethernet MAC address is directly mapped to a policy-tag, site tag, and RF tag.
- **Filter-based association**: Uses regular expressions (regex) to match AP Ethernet MAC addresses. Any AP matching the pattern receives the assigned tags (policy-tag, site tag, and RF tag) configured through an AP filter.
- **AP-based association**: Tag names are pre-configured at the Plug and Play (PnP) server. The AP stores these and submits the tag name during the discovery process.
- **Location-based association**: Tags are mapped to specific locations. Any AP mapped to a location receives the corresponding tags.

Note

Before downgrading from Cisco IOS XE 26.1.1 or later to Cisco IOS XE 17.18.x or earlier, explicitly assign the required policy, site, and RF tags to each access point that has a statically configured name. Otherwise, an AP whose tags are assigned through an AP filter or location configuration receives the default tags after the downgrade.

Effect of AP tag modification

Modifying an AP tag results in DTLS connection reset, forcing the AP to rejoin the controller. If only one tag is specified in the configuration, default tags are used for other types, for example, if only policy tag is specified, the default-site-tag and default-rf-tag will be used for site tag and RF tag.

Modifying an AP tag has these effects:

- It resets the DTLS connection, forcing the AP to rejoin the controller.
- If only one tag is specified (for example, only a policy tag), the system assigns default tags for the other types:
  - The default-site-tag is used for the site tag.
  - The default-rf-tag is used for the RF tag.

Configure a wireless profile policy (GUI)

Provides comprehensive configuration procedures for wireless profile policies, flex profiles, AP profiles, user management, password encryption, and RF profiles through GUI and CLI interfaces.

Define and apply a wireless profile policy to manage network behavior and access for wireless clients.

Use this task to create or modify a policy profile, ensuring wireless network policies suit your organization's needs.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click **Add**.
3. In the **Add Policy Profile** window, in **General** tab, enter a name and description for the policy profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces. Do not use spaces as it causes system instability.
4. To enable the policy profile, set **Status** as **Enabled**.
5. Use the slider to enable or disable **Passive Client** and **Encrypted Traffic Analytics**.
6. In the **CTS Policy** section, choose the appropriate status for the following:
   - Inline Tagging–a transport mechanism using which a controller or access point understands the source SGT.
   - SGACL Enforcement
7. Specify a default **SGT**. The valid range is from 2 to 65519.
8. In the WLAN Switching Policy section, choose the following, as required:
   - Central Switching: Tunnels both the wireless user traffic and all control traffic via CAPWAP to the centralized controller where the user traffic is mapped to a dynamic interface/VLAN on the controller. This is the normal CAPWAP mode of operation.

- Central Authentication: Tunnels client data to the controller, as the controller handles client authentication.
- Central DHCP: The DHCP packets received from AP are centrally switched to the controller and then forwarded to the corresponding VLAN based on the AP and the SSID.
- Central Association Enable: When central association is enabled, all switching is done on the controller.
- Flex NAT/PAT: Enables Network Address Translation(NAT) and Port Address Translation (PAT) mode.

9. Click **Save & Apply to Device**.

The wireless profile policy is successfully created and applied. Devices use the updated policy settings for wireless client management.

Configure a wireless policy profile (CLI)

Configure a Policy Tag using commands.

Define and apply a wireless policy profile on your device using command-line interface commands.

Use this task to configure wireless profile policies on Cisco wireless controllers. Policy profiles specify settings such as VLAN mapping, idle timeouts, and accounting lists for wireless networks.

> **Note**
>
> When a client moves from an old controller to a new controller (managed by Cisco Prime Infrastructure), the old IP address of the client is retained, if the IP address is learned by ARP or data gleaning. To avoid this scenario, ensure that you enable **ipv4 dhcp required** command in the policy profile. Otherwise, the IP address gets refreshed only after a period of 24 hours.

Follow the procedure given to configure a wireless profile policy:

Before you begin

- Ensure you have administrator privileges to access and configure the device.
- Have the required VLAN ID, idle timeout value, and accounting list details available, if applicable.

Follow these steps to configure a wireless profile policy:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enters wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy rr-xyz-policy-1
   ```

3. Optional: Configure the duration of idle timeout in seconds.

   Example

   ```
   Device(config-wireless-policy)# idle-timeout 1000
   ```

4. Configure the VLAN name or VLAN ID.

   Example

   ```
   Device(config-wireless-policy)# vlan 24
   ```

5. Set the accounting list for IEEE 802.1x.

   Example

   ```
   Device(config-wireless-policy)# accounting-list user1-list
   ```

6. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

7. Optional: View detailed information about a policy profile, using the **show wireless profile policy detailed** *policy-profile-name* command.

   Example

   ```
   Device# show wireless profile policy summary
   ```

The wireless policy profile is configured and enabled on the device. All specified settings are applied to the selected policy.

What to do next

- Associate the policy profile with a WLAN as needed.
- Review and validate the applied settings by connecting a client device and confirming expected behavior.

Configure a flex profile (GUI)

Configure a Flex Profile using GUI.

Create or modify a flex profile to customize wireless network behavior for specific sites or device groups.

Use flex profiles within your network management system to define site-specific configurations such as VLANs, SSIDs, or access policies.

Before you begin

Identify the devices or sites to apply the flex profile.

Procedure

1. Choose **Configuration > Tags & Profiles** > **Flex**.
2. Click **Add**.
3. Enter the **Name** of the flex profile. Use ASCII characters from 32 to 126. Do not include leading and trailing spaces.
4. In the **Description** field, enter a description for the flex profile.
5. Click **Apply to Device**.

The flex profile is created or updated and available for assignment to devices or sites.

What to do next

Assign the flex profile to the relevant site, device, or group as needed.

Configure a flex profile

Configure a flex profile using commands.

Create or modify a flex profile to customize wireless network behavior for specific sites or device groups.

Use flex profiles within your network management system to define site-specific configurations such as VLANs, SSIDs, or access policies.

Before you begin

Identify the devices or sites to apply the flex profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a flex profile and enter flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex rr-xyz-flex-profile
   ```

3. Optional: Enable default parameters for the flex profile.

   Example

   ```
   Device(config-wireless-flex-profile)# description xyz-default-flex-profile
   ```

4. Optional: Enable ARP caching.

   Example

   ```
   Device(config-wireless-flex-profile)# arp-caching
   ```

5. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-wireless-flex-profile)# end
```

6. Optional: View detailed parameters about the flex profile, use the **show wireless profile flex detailed** *flex-profile-name* command.

Example

```
Device# show wireless profile flex summary
```

The flex profile is created or updated and available for assignment to devices or sites.

What to do next

Assign the flex profile to the relevant site, device, or group as needed.

Configure an AP profile (GUI)

Configure an AP Profile using GUI.

Configure and customize AP join profiles for your wireless deployment.

Use this task to define, modify, or apply AP profile parameters such as country code, LED state, timers, VLAN tagging, security settings, management options, and advanced features, using the device's graphical interface.

Before you begin

- Review the default AP join profile to update parameters for your environment (For example, Control and Provisioning of Wireless Access Points (CAPWAP), IPv4 or IPv6, UDP Lite, High Availability, retransmit configuration parameters, global AP failover, Hyperlocation configuration parameters, Telnet or SSH, 11u parameters, and so on.)
- Obtain required information, such as network-specific settings, controller addresses, credentials, and profile names.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join Profile** window, click **Add**.

   The **Add AP Join Profile** window is displayed.

   > **Note**
   >
   > DHCP fallback is enabled by default. If an AP is assigned a static IP address and unable to reach the controller, the AP falls back to the DHCP. To prevent an AP from switching the static IP to DHCP, you must disable the DHCP fallback configuration in an AP join profile.

3. In the **General** tab, enter a name and description for the AP join profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.

4. Check the **LED State** check box to set the LED state of all APs connected to the device to blink, making them easier to locate. The LED state is enabled by default.
5. In the **Client** tab and **Statistics Timer** section, enter the time in seconds that the AP sends its 802.11 statistics to the controller.
6. In the **TCP MSS Configuration** section, check the **Adjust MSS Enable** check box to enter value for Adjust MSS. You can enter or update the maximum segment size (MSS) for transient packets that traverse a router. TCP MSS adjustment enables the configuration of the maximum segment size (MSS) for transient packets that traverse a router, specifically TCP segments with the SYN bit set.

   In a CAPWAP environment, a lightweight AP discovers a device by using CAPWAP discovery mechanisms, and then sends a CAPWAP join request to the device. The device sends a CAPWAP join response to the AP that allows the AP to join the device.

   When the AP joins the device, the device manages its configuration, firmware, control transactions, and data transactions.

7. In the **CAPWAP** tab, you can configure these options:

   - High Availability

     You can configure primary and secondary backup controllers for all APs (which are used if primary, secondary, or tertiary controllers are not responsive) in this order: primary, secondary, tertiary , primary backup, and secondary backup.In addition, you can configure various timers, including heartbeat timers and discovery request timers. To reduce the controller failure detection time, you can configure the fast heartbeat interval (between the controller and the AP) with a smaller timeout value. When the fast heartbeat timer expires (at every heartbeat interval), the AP determines if any data packets have been received from the controller within the last interval. If no packets have been received, the AP sends a fast echo request to the controller.

   a) In the **High Availability** tab, enter the time (in seconds) in the **Fast Heartbeat Timeout** field to configure the heartbeat timer for all APs. Specifying a small heartbeat interval reduces the amount of time it takes to detect device failure.

   > **Note**
   >
   > Configure **Fast Heartbeat Timeout** to assist AP in sending primary discovery request periodically to the configured backup controllers along with the primary, secondary, and tertiary-base controllers.

   b) In the **Heartbeat Timeout** field, enter the time in seconds to configure the heartbeat timer for all APs. Specifying a small heartbeat interval reduces the amount of time it takes to detect device failure.
   c) In the **Discovery Timeout** field, enter a value between one and 10 seconds (inclusive) to configure the AP discovery request timer.
   d) In the **Primary Discovery Timeout** field, enter a value between 30 and 3000 seconds (inclusive) to configure the AP primary discovery request timer.
   e) In the **Primed Join Timeout** field, enter a value between 120 and 43200 seconds (inclusive) to configure the AP primed join timeout.
   f) In the **Retransmit Timers Count** field, enter the number of times that you want the AP to retransmit the request to the device and vice versa. Valid range is between three and eight.
   g) In the **Retransmit TimersInterval** field, enter the time duration between retransmission of requests. Valid range is between two and five.
   h) Check the **Enable Fallback** check box to enable fallback.
   i) Enter the **Primary Controller** name and IP address.
   j) Enter the **Secondary Controller** name and IP address.
   k) Click **Save & Apply to Device**.

> **Note**
>
> The primary and secondary settings in the AP join profile are not used for AP fallback. This means that the AP will not actively probe for those controllers (which are a part of the AP join profile), when it has joined one of them.
>
> This setting is used only when the AP loses its connection with the controller, and then prioritizes which other controller it should join. These controllers have a priority of four and five, following APs in the **High Availability** tab of the AP page.
>
> The APs that are added as the primary, secondary, and tertiary APs in the **High Availability** tab of the AP configuration page, are actively probed and are used for the AP fallback option.

- Advanced

a) In the **Advanced** tab, check the **Enable VLAN Tagging** check box to enable VLAN tagging.
b) Check the **Enable Data Encryption** check box to enable Datagram Transport Layer Security (DTLS) data encryption.
c) Check the **Enable Jumbo MTU** to enable large maximum transmission unit (MTU). The MTU is the largest physical packet size, measured in bytes, that a network can transmit. Any messages larger than the MTU are divided into smaller packets before transmission. Jumbo frames exceed the standard Ethernet frame size, which is 1518 bytes (including Layer 2 (L2) header and FCS). Because vendors may have different frame size definitions, jumbo frames are not standardized by IEEE.
d) Use the **Link Latency** drop-down list to select the link latency. Link latency monitors the round-trip time of the CAPWAP heartbeat packets (echo request and response) from the AP to the controller and back.
e) From the **Preferred Mode** drop-down list, choose the mode.
f) Click **Save & Apply to Device**.

8. In the **AP** tab, you can configure these options:

- General

a) In the **General** tab, check the **Switch Flag** check box to enable switches.
b) Check the **Power Injector State** check box if power injector is being used. Use power injectors to provide flexible powering options for APs, such as local power, multiport switches with inline power, or multiport power patch panels.

   Power Injector Selection parameter enables you to protect your switch port from an accidental overload if the power injector is inadvertently bypassed.

c) From the **Power Injector Type** drop-down list, choose power injector type from these options:

   - Installed–This option examines and remembers the MAC address of the currently connected switch port and assumes that a power injector is connected. Choose this option if your network contains older Cisco 6-Watt switches and you want to avoid possible overloads by forcing a double-check of any relocated APs.

     If you want to configure the switch MAC address, enter the MAC address in theInjector Switch MAC Address text box. If you want the AP to find the switch MAC address, leave theInjector Switch MAC Address text box blank.

> **Note**
>
> Each time an AP is relocated, the MAC address of the new switch port fails to match the remembered MAC address, and the AP remains in low-power mode. You must then physically verify the existence of a power injector and reselect this option to cause the new MAC address to be remembered.

- Override–This option allows the AP to operate in high-power mode without first verifying a matching MAC address. You can use this option if your network does not contain any older Cisco 6-W switches that could be overloaded if connected directly to a 12-W AP. The advantage of this option is that if you relocate the AP, it continues to operate in high-power mode without any further configuration. The disadvantage of this option is that if the AP is connected directly to a 6-W switch, an overload occurs.

d) In the**Injector Switch MAC** field, enter the MAC address of the switch either in xx:xx:xx:xx:xx:xx, xx-xx-xx-xx-xx-xx, or xxxx.xxxx.xxxx format.
e) From the **EAP Type** drop-down list, choose the EAP type as *EAP-FAST* , *EAP-TLS* , or *EAP-PEAP*.
f) From the **AP Authorization Type** drop-down list, choose the type as either *CAPWAP DTLS +* or *CAPWAP DTLS*.
g) In the **Client Statistics ReportingInterval** section, enter the interval for 5 GHz and 2.4 GHz radios in seconds.
h) Check the **Enable** check box to enable extended module.
i) From the **Profile Name** drop-down list, choose a profile name for mesh.
j) Click **Save & Apply to Device**.

- Hyperlocation: Cisco Hyperlocation is a location solution that allows to track the location of wireless clients with the accuracy of one meter. Selecting this option disables all other fields in the screen, except NTP Server.

a) In the **Hyperlocation** tab, check the **Enable Hyperlocation** check box.
b) Enter the **Detection Threshold** value to filter out packets with low RSSI. The valid range is -100 dBm to -50 dBm.
c) Enter the **Trigger Threshold** value to set the number of scan cycles before sending a BAR to clients. The valid range is zero to 99.
d) Enter the **Reset Threshold** value to reset value in scan cycles after trigger. The valid range is zero to 99.
e) Enter the **NTP Server** IP address.
f) Click **Save & Apply to Device**.

- BLE: If your APs are Bluetooth Low Energy (BLE) enabled, they can transmit beacon messages that are packets of data or attributes transmitted over a low energy link. These BLE beacons are frequently used for health monitoring, proximity detection, asset tracking, and in-store navigation. For each AP, you can customize BLE Beacon settings configured globally for all APs.

a) In the **BLE** tab, enter a value in the **BeaconInterval** field to indicate how often you want your APs to send out beacon advertisements to nearby devices. The range is from one to 10, with a default value of one.
b) In the **Advertised Attenuation Level** field, enter the attenuation level. The range is from 40 to 100, with a default of 59.
c) Click **Save & Apply to Device**.

- Packet Capture: Packet Capture feature allows to capture the packets on the AP for the wireless client troubleshooting. The packet capture operation is performed on the AP by the radio drivers on the current channel on which it is operational, based on the specified packet capture filter.

a) In the **Packet Capture** tab, choose an **AP Packet Capture Profile** from the drop-down list.
b) You can also create a new profile by clicking the **+** sign.
c) Enter a name and description for the AP packet capture profile.

d) Enter the **Buffer Size**.
e) Enter the **Duration**.
f) Enter the **Truncate Length** information.
g) In the **Server IP** field, enter the IP address of the TFTP server.
h) In the **File Path** field, enter the directory path.
i) Enter the username and password details.
j) From the **Password Type** drop-down list, choose the type.
k) In the **Packet Classifiers** section, use the option to select or enter the packets to be captured.
l) Click **Save**.
m) Click **Save & Apply to Device**.

9. In the **Management** tab, you can configure these options:

- Device

a) In the **Device** tab, enter the **IPv4/IPv6 Address** of the TFTP server, **TFTP Downgrade** section.
b) In the **Image File Name** field, enter the name of the software image file.
c) From the **Facility Value** drop-down list, choose the appropriate facility.
d) Enter the IPv4 or IPv6 address of the host.
e) Choose the appropriate **Log Trap Value**.
f) Enable Telnet, SSH or both configurations, if required.
g) Enable core dump, if required.
h) Click **Save & Apply to Device**.

- User

a) In the **User** tab, enter username and password details.
b) Choose the appropriate password type.
c) In the **Secret** field, enter a custom secret code.
d) Choose the appropriate secret type.
e) Choose the appropriate encryption type.
f) Click **Save & Apply to Device**.

- Credentials

a) In the **Credentials** tab, enter local username and password details.
b) Choose the appropriate local password type.
c) Enter 802.1x username and password details.
d) Choose the appropriate 802.1x password type.
e) Enter the time in seconds after which the session should expire.
f) Enable local credentials, 802.1x credentials, or both as required.
g) Click **Save & Apply to Device**.

- CDPInterface

a) In the **CDPInterface** tab, enable the CDP state, if required.
b) Click **Save & Apply to Device**.

10. In the **Rogue AP** tab, check the **Rogue Detection** check box to enable rogue detection.

11. In the **Rogue Detection Minimum RSSI** field, enter the RSSI value.

This field specifies the minimum RSSI value for which a Rogue AP should be reported. All Rogue APs with RSSI lower than what is configured will not be reported to controller.

12. In the **Rogue Detection TransientInterval** field, enter the transient interval value.

This field indicates how long the Rogue AP should be seen before reporting the controller.

13. In the **Rogue Detection ReportInterval** field, enter the report interval value.

    This field indicates the frequency (in seconds) of Rogue reports sent from AP to controller.

14. Check the **Rogue Containment Automatic Rate Selection** check box to enable rogue containment automatic rate selection.

    The AP selects the best rate for the target Rogue, based on its RSSI.

15. Check the **Auto Containment on FlexConnect Standalone** check box to enable the feature.

    The AP continues containment if it moves to FlexConnect standalone mode.

16. Click **Save & Apply to Device**.

The AP join profile is created or updated. Devices assigned to this profile use its configuration for network operation and management.

What to do next

- Verify that APs have successfully joined and received the new settings by reviewing AP status.
- Adjust profile settings as necessary for site-specific needs or to resolve configuration issues.

Configure an AP profile (CLI)

Configure an AP Profile using commands.

Set up and customize an AP profile using CLI commands to apply network-wide AP configurations.

Use this procedure when you need to define or modify an AP profile for your wireless controller, typically to standardize AP settings or apply feature-specific options.

Before you begin

Identify the name and required settings for your AP profile.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile xyz-ap-profile
   ```

> **Note**
>
> - In an AP profile, the **EAP-FAST** is the default EAP type.
> - When you delete a named profile, the APs associated with that profile does not revert to the default profile.

3. Add a description for the AP profile.

   Example

   ```
   Device(config-ap-profile)# description "xyz ap profile"
   ```

4. Configure DHCP fallback.

   Example

   ```
   Device(config-ap-profile)# ip dhcp fallback
   ```

   > **Note**
   >
   > DHCP fallback is enabled by default. If an AP is assigned a static IP address and cannot reach the controller, the AP falls back to the DHCP. To prevent an AP from switching from a static IP to DHCP, disable the DHCP fallback configuration in an AP join profile.

5. Enable CDP for all Cisco APs.

   Example

   ```
   Device(config-ap-profile)# cdp
   ```

6. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

7. Optional: Display detailed information about an AP join profile.

   Example

   ```
   Device# show ap profile name xyz-ap-profile detailed
   ```

The AP profile is created or updated with specified settings, and changes are active on the controller.

What to do next

Assign APs to the new profile as required, and verify AP behavior matches the intended configuration.

Configure user for AP management (CLI)

Configure the AP Management using commands.

Set up a management user account to centrally control APs through CLI.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile, and then enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Specify the AP management username and password for managing all of the APs configured to the controller.

   Example

   ```
   Device(config-ap-profile)# mgmtuser username myusername password 0 12345678
   ```

   - **0**: Specifies an UNENCRYPTED password.
   - **8**: Specifies an AES encrypted password.

   > **Note**
   >
   > While configuring a username, ensure that you do not use special characters. Using special characters may cause a configuration error.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(configure-ap-profile)# end
   ```

The AP management user is configured for all APs that are managed by the controller.

Set a private configuration key for password encryption

Configure a Private Configuration key for Password Encryption.

Configure a private configuration key to enable password encryption on the device.

Use this task to set or change a private key used for encrypting passwords. You must do this before you enable AES password encryption.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the password encryption keyword.

   Example

   ```
   Device(config)# key config-key password-encrypt 12345678
   ```

   Here, *config-key* refers to any key value with at least eight characters.

   Note

   The *config-key* value must not begin with these special characters:

   - !
   - #
   - ;

3. Enable the encrypted pre-shared key.

   Example

   ```
   Device(config)# password encryption aes
   ```

4. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

You have now enabled password encryption using your specified private configuration key.

What to do next

You can now enable AES password encryption, if needed.

Configure an RF profile (GUI)

Configure an RF profile using GUI.

Create and enable an RF profile to optimize radio frequency settings for your wireless network.

Use this task to define an RF profile that sets parameters for radio bands and device operation. This ensures consistent performance across your wireless deployment.

Before you begin

Use the same RF profile name when configuring the wireless RF tag. If the RF tag contains an RF profile that does not exist, the radios do not operate.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF**.
2. On the **RF Profile** window, click **Add**.
3. In the **General** tab, enter a name for the RF profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
4. Choose the appropriate **Radio Band**.
5. To enable the profile, set the status as **Enable**.
6. Enter a **Description** for the RF profile.
7. Click **Save & Apply to Device**.

The new RF profile is created, enabled, and applied to the device.

What to do next

- Verify that the RF profile settings are visible and active on your device.
- Assign the profile to RF tags or APs, if required, to complete your configuration.

Configure an RF profile (CLI)

Configure an RF profile using commands.

Create and enable an RF profile to optimize radio frequency settings for your wireless network.

Use this task to define an RF profile that sets parameters for radio bands and device operation. This ensures consistent performance across your wireless deployment.

Before you begin

Use the same RF profile name when configuring the wireless RF tag. If the RF tag contains an RF profile that does not exist, the radios do not operate.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile, and enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile rfprof24_1
   ```

   Note

   Use the **24ghz** command to configure the 802.11b parameters. Use the **5ghz** command to configure the 802.11a parameters. Use the **6ghz** command to configure the 802.11 6-GHz parameters.

3. Optional: Enable default parameters for the RF profile.

   Example

   ```
   Device(config-rf-profile)# default
   ```

4. Enable the RF profile on the device.

   Example

   ```
   Device(config-rf-profile)# no shutdown
   ```

5. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-rf-profile)# end
   ```

6. Optional: Display a summary of available RF profiles.

   Example

   ```
   Device# show ap rf-profile summary
   ```

7. Optional: Display detailed information about a particular RF profile.

   Example

   ```
   Device# show ap rf-profile name rfprof24_1 detail
   ```

You have created and enabled a new RF profile, and applied it to the device.

What to do next

- Verify that the RF profile settings are visible and active on your device.
- Assign the profile to RF tags or APs as required to complete your configuration.

Configure a site tag (GUI)

Guides through configuring site tags, policy tags, wireless RF tags via GUI and CLI, and demonstrates attaching policy and site tags to access points.

Create and apply a site tag to organize and manage APs within your wireless network.

Use site tags to assign AP join profiles and control plane names to APs, supporting flexible network segmentation and management.

Before you begin

Confirm required AP join profiles and control plane names are already set up.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page, click the **Site** tab.
3. Click **Add** to view the **Add Site Tag** window.
4. Enter a name and description for the site tag. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
5. Choose the required **AP Join Profile** to be attached to the site tag.
6. Choose the required **Control Plane Name**.
7. If required, enable the **Local Site**.

   If you disable Local Site, the site is remote and the deployment uses FlexConnect mode.
8. Click **Save & Apply to Device** .

The site tag is created and applied to the device. The selected AP join profile and control plane name are now associated with the site tag.

What to do next

Verify that your APs are assigned to the correct site tag and check their operational status in the device list.

Configure a site tag for FlexConnect APs (CLI)

Configure a Site Tag using CLI.

Set up a site tag for wireless deployments to enable site-specific configurations using the CLI.

Before you begin

Gather required information, such as the desired site tag name and flex profile name.

Procedure

1. Enter global configuration mode.

   Example

```
Device# configure terminal
```

2. Configure a site tag and enter site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site rr-xyz-site
   ```

3. Configure a flex profile.

   Example

   ```
   Device(config-site-tag)# flex-profile rr-xyz-flex-profile
   ```

   - You cannot remove flex profile configurations from a site tag that is configured as a local site.

     Use the **no local-site** command to remove local site configurations before applying flex profile configurations.

4. Add a description for the site tag.

   Example

   ```
   Device(config-site-tag)# description "default site tag"
   ```

5. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-site-tag)# end
   ```

6. Optional: Display the number of site tags.

   Example

   ```
   Device# show wireless tag site summary
   ```

The site tag is configured on the device, and site-specific settings are applied.

Configure policy tag (GUI)

Configure a Policy Tag using the GUI.

Create and apply a policy tag to group wireless local area network (WLAN) and policy profiles for your network configuration.

Use this task when you need to define or update policy tags for your wireless network devices using the GUI.

Before you begin

- Prepare unique names for policy tags using ASCII characters (32 to 126, no leading or trailing spaces).
- Identify the WLAN and policy profiles you plan to map.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Tags** > **Policy**.

2. Click **Add** to view the **Add Policy Tag** window.
3. Enter a name and description for the policy tag. You can use ASCII characters from 32 to 126, but do not include any leading or trailing spaces.
4. Click **Add** to map WLAN and policy.
5. Choose the WLAN profile to map with the appropriate policy profile, and click the tick icon.
6. Click **Save & Apply to Device**.

Your device has the new policy tag applied. The mapped WLAN and policy profiles are now active based on your configuration.

What to do next

Verify that connected devices use the updated policy tag and that expected network policies are enforced.

Configure a policy tag (CLI)

Configure a policy tag using commands.

Create and apply a policy tag to group wireless local area network (WLAN) and policy profiles for your network configuration.

Use this task when you need to define or update policy tags for your wireless network devices using the CLI.

Before you begin

- Prepare unique names for policy tags using ASCII characters (32 to 126, no leading or trailing spaces).
- Identify the WLAN and policy profiles you plan to map.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config-policy-tag)# wireless tag policy default-policy-tag
   ```

   Note

   When performing local web authentication, the clients connected to a controller get disconnected intermittently before session timeout.

3. Add a description to a policy tag.

Example

```
Device(config-policy-tag)# description "default-policy-tag"
```

4. Map a remote-LAN profile to a policy profile.

   Example

   ```
   Device(config-policy-tag)# remote-lan remote-lan-name policy
   profile-policy-name port-id port-id-number
   ```

5. Map a policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan wlan-name policy profile-policy-name
   ```

   > **Note**
   >
   > Ensure that the WLAN profile is not used by any other profiles. If the AP uses the default profile, ensure that the **no central switching** command is configured on other profiles.

6. Exit policy tag configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-policy-tag)# end
   ```

7. Optional: Display the configured policy tags.

   Example

   ```
   Device# show wireless tag policy summary
   ```

   > **Note**
   >
   > To view detailed information about a policy tag, use the **show wireless tag policy detailed** *policy-tag-name* command.

Your device has the new policy tag applied. The mapped WLAN and policy profiles are now active based on your configuration.

What to do next

Verify that connected devices use the updated policy tag and the expected network policies are applied.

Configure wireless RF tag (GUI)

Configure an RF (Radio frequency) Tag using GUI.

Create and apply an RF tag that defines radio frequency profiles for device groups.

Procedure

1. a) Choose **Configuration** > **Tags & Profiles** > **Tags** > **RF**.
2. Click **Add** to view the **Add RF Tag** window.
3. Enter a name and description for the RF tag. The name can be ASCII characters from 32 to 126 and must not include leading or trailing spaces.
4. Choose the required **5 GHz Band RF Profile**, **5 GHz Band RF Profile**, and **2.4 GHz Band RF Profile** to be associated with the RF tag.
5. Click **Update & Apply to Device**.

The RF tag is created with the specified RF profiles and applied to the device.

Configure wireless RF tag (CLI)

Configure a RF (Radio frequency) Tag using commands.

Assign and configure an radio frequency (RF) tag on your wireless device using the CLI, to manage radio profile settings per tag.

Perform this task to create or modify a wireless RF tag. This allows you to apply specific 2.4 GHz, 5 GHz, or 6 GHz RF profiles to associated APs.

Before you begin

- You can use only two profiles (2.4-GHz and 5-GHz band RF profiles) in an RF tag.
- You can use only three profiles (2.4-GHz, 5-GHz and 6-GHz band RF profiles) in an RF tag.
- Ensure you use the same AP tag name you created during the AP configuration task.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an RF tag to enter wireless RF tag configuration mode.

   Example

   ```
   Device(config)# wireless tag rf rftag1
   ```

3. Attach an IEEE 802.11b RF policy to the RF tag.

Example

```
Device(config-wireless-rf-tag)# 24ghz-rf-policy rfprof24_1
```

To configure a dot11a policy, use the **5ghz-rf-policy** command. To configure a 6GHz radio dot11 policy, use the **6ghz-rf-policy** command.

4. Add a description for the RF tag.

   Example

   ```
   Device(config-wireless-rf-tag)# description Test
   ```

5. Exit configuration mode to return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-rf-tag)# end
   ```

6. Display the available RF tags.

   Example

   ```
   Device# show wireless tag rf summary
   ```

7. Display detailed information of a particular RF tag.

   Example

   ```
   Device# show wireless tag rf detailed rftag1
   ```

You have configured the RF tag and it is now available for assignment.

What to do next

Assign the RF tag to the appropriate AP tag or APs if you have not already done so.

Attach a policy tag and site tag to an AP (GUI)

Attach a Policy Tag and Site Tag to an AP using GUI.

Assign a policy tag and site tag to an AP using the GUI.

Use this procedure to associate specific network policies and locations with an AP in your Cisco wireless deployment.

Before you begin

Make sure you have the wired MAC address of the AP.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.

   The **All Access Points** section displays details of all the APs on your network.

2. To edit the configuration details of an AP, select the row for that AP.

   The **Edit AP** window is displayed.

3. In the **General** tab and **Tags** section, specify the appropriate policy, site, RF tags, and radio profile that you created on the **Configuration** > **Tags & Profiles** > **Tags** window.
4. Click **Update & Apply to Device**.

   Note

   To see the policy tag, site tag, or the RF tag that is applied to the AP through the GUI, refresh the GUI window.

The AP is now associated with the specified policy, site, and optionally RF tags you selected.

Attach policy tag and site tag to an AP (CLI)

Attach Policy Tag and Site Tag to an AP using commands.

Assign a policy tag and site tag to an AP using the CLI.

Use this procedure to associate specific network policies and locations with an AP in your Cisco wireless deployment.

Before you begin

Make sure you have the wired MAC address of the AP.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco AP and enters AP profile configuration mode.

   Example

   ```
   Device(config)# ap F866.F267.7DFB
   ```

   Note

   The *mac-address* should be a wired mac address.

3. Map a policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag rr-xyz-policy-tag
   ```

4. Map a site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag rr-xyz-site
   ```

5. Associate the RF tag.

   Example

   ```
   Device(config-ap-tag)# rf-tag rf-tag1
   ```

6. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

7. Optional: Display AP details and the tags associated to it.

   Example

   ```
   Device# show ap tag summary
   ```

8. Display the AP name with tag information.

   Example

   ```
   Device# show ap name "ap-name" tag info
   ```

9. Optional: Display the AP name with tag details.

   Example

   ```
   Device# show ap name ap-name tag detail
   ```

The AP is now associated with the specified policy, site, and optionally, RF tags you selected

Enhanced site tag-based load balancing

Explains enhanced site tag-based load balancing concepts, prerequisites, use cases, configuration procedures, and verification commands for optimizing wireless network performance.

A site tag-based load balancing is a controller mechanism that

- distributes APs across Wireless Network Control Daemon (WNCD) processes based on site tags,
- allows configuration of a site load for each site tag to optimize AP assignment considering site size, and
- automatically retains site tags in persistent memory and balances them during controller bootup in descending order of the configured site load.

The controller takes the load balancing decision for a site tag when the first AP from that site tag joins.

Table 5: Feature History

Feature	Release	Feature Information
Enhanced Site Tag-Based Load Balancing	Cisco IOS XE Dublin 17.10.1	When the first AP from a site joins the controller, it takes the decision to load balance the entire site. However, this is done without knowing the site load.

How controllers functioned before load balancing

Previously, controllers did not consider the actual size of sites when making load balancing decisions. The system functioned optimally only when all sites were of approximately equal size. Unequal distribution caused some WNCDs to be overloaded while others remained underused.

The enhanced feature enables administrators to specify a site load for each site tag, ensuring the controller takes site size into account when distributing APs and thus resulting in improved load distribution among WNCDs.

Behavior during controller reboot

- After you configure site load balancing in one or more site tags and reboot the controller, The feature retains actively used site tags and balances them at bootup by prioritizing those with higher configured site load before any APs join.
- If load balancing is configured for a site tag with APs already joined, load balancing assignments remain unchanged unless all APs, including those not in the site tag, disconnect or the controller is rebooted.

assigning a higher site load to one site over the other

Suppose Site Tag X is assigned a higher site load than Site Tag Y. Upon controller bootup, APs from Site Tag X are distributed among WNCDs before those from Site Tag Y, helping prevent excessive load on any single WNCD even if Site Tag X contains many more APs than Site Tag Y.

Analogy: assigning classes to school buses

Think of enhanced site tag-based load balancing like assigning students from different-sized classes (site tags) to school buses (WNCDs). If you ignore class size, you might put all students from the largest class on a single bus, overloading it while leaving other buses half empty. By taking class sizes into account when assigning students, you distribute them more evenly and efficiently among the buses, preventing overcrowding and making better use of all resources. Similarly, by setting site load values, the controller assigns APs more fairly to WNCDs, balancing the work and avoiding overload.

Prerequisites for Enhanced Site Tag-Based Load Balancing

Enhanced Site Tag-Based load balancing feature prerequisites.

- Ensure that you configure the site load.
- We recommended that you configure all the named sites with a load value.

> **Note**
>
> The configured load is only an estimate. It will only be used for site load balancing. Specifically, it does not prevent APs, or clients from joining or associating.

Use cases

The two Use Cases for Site Load Balancing.

The site load configuration uses a load factor instead of an absolute number to address different use cases. Although the load factor does not have to match the number of APs in a site, using the AP count often provides a practical approximation of the site load.

Here are the use cases:

- Sites with normal client density and roaming load can use AP count as a good approximation of site load. Examples include cubicle areas in offices and hospitals.
- For sites with high client density and roaming load, configure a load factor greater than the number of APs. For example, when a site has 200 APs, use a load factor of 300 or 400 to accommodate the increased client load. Examples include stadiums, cafeterias, and conference floors.

Configure site load (CLI)

Configure Site Load in the Controller Console using commands.

Assign a relative load value to a site tag using CLI. This helps the system optimize resource allocation and network performance for wireless deployments.

Use this task when you need to set or adjust the load recommendation for a specific site on your wireless controller. The load value influences how resources are distributed across sites.

Before you begin

Identify the name of the site tag you want to configure.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure site tag and enter site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site area1
   ```

3. Configure the site load.

Example

```
Device(config-site-tag)# load 200
```

The *load* is the estimate of the relative load reserved for the site. Values range between zero to 1000. The default value zero means no load recommendation for the site.

4. Return to privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

The controller uses the configured load value for the specified site tag to optimize network resource allocation for that site

What to do next

Optionally, verify your changes by displaying the site tag configuration and confirming the new load value.

Verify enhanced site tag-based load balancing configuration

Verify Site Load Balancing Configuration in the Controller Console.

To view detailed information about a site, use the command:

```
Device# show wireless tag site detailed area1
Site Tag Name        : area1
Description          :
---------------------------------------
AP Profile           : default-ap-profile
Local-site           : Yes
Image Download Profile: default
Fabric AP DHCP Broadcast : Disabled
Fabric Multicast Group IPv4 Address : 239.1.1.1
Site Load            : 200
```

To view the default site tag type for Wireless Network Controller daemon (WNCD) instances, use the command:

```
Device# show wireless loadbalance tag affinity
Tag           Tag type    No of AP's Joined   Wncd Instance
-----------------------------------------------------------------------
area1         SITE TAG                  50         0
area2         SITE TAG                  50         0
area3         SITE TAG                  100        1
area4         SITE TAG                  150        2
```

Wireless radio profiles

Describes wireless radio profile functionality, restrictions, configuration procedures for beam selection, antenna count settings, per-radio per-slot RF tag profiles, and verification methods.

A wireless radio profile is a configuration profile that

- defines radio parameters and beam steering settings for APs with specific antennae

- enables administrators to select antenna count, beam selection mode, and beam direction for supported APs, and
- allows application of customized radio settings to AP slots through RF tag configurations.

Table 6: Feature history Table

Feature Name	Release	Description
Cisco IOS XE 17.6.1	C-ANT9104 antenna support along with beam width and antenna count configuration on the controller	With this feature • you can configure radio profiles for beam-selection APs with the C-ANT9104 antenna. • you can configure antenna count for Cisco Catalyst 9124AXI/D outdoor APs • you can configure the antenna beam-selection for the 5-GHz slots–slot 1 and slot 2, and • you must explicitly configure the beam selection mode for APs with the C-ANT9104 antenna, as there is no default value for the beam-selection configuration.

Beam steering modes

The C-ANT9104 antenna-enabled Cisco Catalyst 9130AX Series APs have precise control over the antennae pattern. You can thus configure the beam-steering direction for the antennae on the controller. The C-ANT9104 antenna-enabled Cisco Catalyst 9130AX Series APs can operate on these beam-steering modes:

- Wide beam
- Narrow beam
- Narrow beam with 10 degrees tilt
- Narrow beam with 20 degrees tilt

After you create the radio profile, link the radio profile under the radio frequency (RF) tag configuration, so that the radio profile is applied to the APs.

Analogy: smart lighting presets

A wireless radio profile is like a preset scene on a smart lighting system. It lets you preconfigure a group of lights (APs) for specific conditions–such as brightness, color, and focus–so applying the scene guarantees the desired ambiance every time

Restrictions

- Radio Resource Management (RRM) configuration is not supported for Cisco ANT9104 antennae.

  RRM features such as Dynamic Channel Assignment (DCA), Radio Transmit Power Control (TPC), Flexible Radio Assignment (FRA), and so on, are disabled on C-ANT9104 antenna-enabled Cisco Catalyst 9130 Series APs.
- If the AP enabled with Cisco ANT9104 antenna uses a software version earlier than Cisco IOS XE 17.6.1, the AP can still join the controller. However, the AP does not function as the operation status of the radios is down.

Configure a wireless radio profile (GUI)

Configure a Wireless Radio Profile using GUI.

Create and apply a wireless radio profile using the GUI

Use this task when you need to define or update radio settings on Cisco wireless devices through the GUI.

Before you begin

Confirm the devices support the intended profile settings.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. On the **Radio Profile** window, click **Add** .
3. Enter a name and description for the radio profile.
4. Choose the appropriate **Antenna Beam** selection. Configure this option for APs connected with the C-ANT9104 antenna.

   Note

   The antenna beam selection is set to **Not Configured** if no settings are detected.

5. Enter the number in the **Number of antenna to be enabled** field.

   Note

   The option is available for the Cisco Catalyst 9124AXE Outdoor Access Points.

6. Click **Save & Apply to Device**.

The new wireless radio profile is saved and applied to selected devices.

Configure a radio profile and beam selection

Configure a Wireless Radio Profile using commands.

Set up a wireless radio profile and define antenna beam selection parameters to optimize wireless performance.

Use this task to create or update a wireless radio profile and specify how the antenna selects its transmission beam using CLI commands.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the radio profile to enter the wireless radio profile configuration mode.

Example

```
Device(config)# wireless profile radio wireless-radio-profile
```

3. Configure the beam selection of the antenna under the new radio profile.

Example

```
Device(config-wireless-radio-profile)# antenna beam-selection narrow tilt 10
```

The wireless radio profile is applied with the specified antenna beam selection settings.

Configure the number of antennas in a wireless radio profile

Configure the Antenna Count in a Wireless Radio Profile using commands.

Set the number of antennas to be enabled for each slot in a wireless radio profile.

Perform this task to ensure the correct number of antennas are active on your wireless device, optimizing radio performance according to deployment needs.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the radio profile to enter the wireless radio profile configuration mode.

Example

```
Device(config)# wireless profile radio wireless-radio-profile
```

3. Configure the number of antennas to be enabled under the new radio profile.

Example

```
Device(config-wireless-radio-profile)# antenna count 4
```

The specified number of antennas are enabled under the radio profile, ensuring the wireless device operates with the intended antenna configuration.

Configure a slot for each radio in the RF tag profile

Configure a Radio Profile for each slot in an RF tag using commands.

Assign a radio profile to each slot in an RF tag, ensuring that specific profile configurations are applied to each radio in a wireless network device.

Each radio (such as 2.4 GHz or 5 GHz) in a device slot must be linked to a radio profile that is under an RF tag. This is achieved using the CLI. Applying the correct radio profile for each slot ensures optimal RF behavior and feature settings.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RF tag to enter the wireless RF tag configuration mode.

   Example

   ```
   Device(config)# wireless tag rf wireless-rf-tagname
   ```

3. Configure the 802.11a or 802.11b radio profile.

   Example

   ```
   Device(config-wireless-rf-tag)# dot11 5ghz slot1 radio-profile
   wireless-radio-profile
   ```

You have configured each radio slot under the RF tag with the designated radio profile. The device applies the profile settings to the correct radio.

Verify a radio profile

Verify the summary of all configured radio profiles using commands.

To view the summary of all the configured radio profiles, use the command:

```
Device# show wireless profile radio summary

Number of radio-profiles: 3

Antenna Profile Name             Description
------------------------------------------------------------------------
radio-profile-1                  Custom profile for Slot1

antenna-ewlc                     Add description
default_radio_profile            Preconfigured default radio profile
```

To view detailed information about the parameters configured for a radio profile, use the command:

```
Device# show wireless profile radio detailed radio-profile-name
Radio Profile name                              : radio-profile-1
Description                                     : Custom profile for slot1
Beam-Selection                                  : Wide beam
```

To view radio profile and RF tag information, use the command:

```
Device # show ap name Cisco-AP tag info
AP Name            : Cisco-AP
AP Mac             : 04xx.40xx.XXXX

Applied Tags :
-----------------------------------------
  Tag Type             Tag Name
  -----------------------------------------
  RF Tag               test-rf
  Site Tag             default-site-tag
  Policy Tag           default-policy-tag

Tag/Profile Type Misconfigured
-----------------------------------------
RF Tag No
Policy Tag No
Site Tag No
Flex profile No
AP join profile No
2.4GHz Rf Profile No
5 GHz Rf Profile No
5 GHz Slot1 Radio Profile NO
5 GHz Slot2 Radio Profile Yes

Resolved Tags :
-----------------------------------------
Tag Source         : Static

  Tag Type             Tag Name
  -----------------------------------------
  RF Tag               test-rf
  Site Tag             default-site-tag
  Policy Tag           default-policy-tag
```

To display beam selection and the number of antennas, run the commands:

```
Device# show wireless profile radio detailed radio-profile-1
Radio Profile name : radio-profile-1
Description        : Custom profile for slot1
Beam-Selection     : Wide beam
```

```
Device# show ap name cisco-ap config slot 1 | section 11n
802.11n Antennas
      Number of Antennas selected               : 2
      Supported Antenna  modes                  : 1x1 2x2 4x4
      Antenna port mapping                      : AB
      SIA Status                                : Not Present
```

```
Device# show ap name cisco-ap config slot 1 | include beam
Beam Selection : Narrow from centre 20
```

AP filters

Introduces AP filter concepts and provides procedures for setting tag priority, managing tag precedence, creating AP filters, configuring filter priorities, and verifying configurations.

An AP filter is a global tagging mechanism that

- associates APs with specific tag sources based on defined filter criteria
- organizes and applies tag sources in priority order according to configuration, and
- enables flexible control over which tags are assigned to each AP throughout the device discovery and onboarding process.

Additional reference information

AP filters function similarly to access control lists (ACLs) on the controller and operate at the global level. You can create AP filters based on AP names or other attributes, and incorporate filter criteria into discovery requests. Tag sources for APs can originate from static configuration, the AP filter engine, per-AP Plug and Play (PnP), or default configuration. The AP filter feature determines tag precedence, ensuring the correct tags are assigned according to organizational policies.

You cannot disable the AP filter feature. However, you can configure the priority of tag sources using the **ap filter-priority** <**priority**> <**filter-name**> command.

You can specify tag names at the PnP server (similarly to Flex groups or AP groups). During AP discovery and join requests, the AP stores and sends the allocated tag name as part of the request, allowing for automated and dynamic tag assignment.

Analogy: ticket sorting gate

An AP filter is like a ticket sorting gate at an event venue. Each attendee (AP) presents information at the entrance, and the sorting gate (filter) checks their details to assign them to the right group or area (tag source) based on predefined criteria and priorities. Just as event organizers use sorting gates to efficiently direct attendees, network administrators use AP filters to efficiently assign tags and manage APs in large wireless environments.

Set tag priority (GUI)

Configure Tag Priority using GUI.

Set the order of priority for tag sources in AP configuration using the GUI

Use this task whenever you want to control which tag source is applied first to your AP configurations in the system. This helps ensure the desired tag assignment behavior.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags** > **AP** > **Tag Source**.
2. Drag and drop the tag sources to change priorities.

The system saves and applies the new tag source priority for AP configuration.

Set tag priority

Configure Set Tag Priority using commands.

Resolve ambiguity in tag assignment by defining the priority of tag sources for access points.

When an AP joins the wireless controller, it picks up tags from multiple sources. Setting tag source priorities ensures APs use tags from the preferred source. If you do not configure precedence, default priorities are used.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Optional: Configure AP tag source priority. Default priorities for Static, Filter, and PnP.

   Example

   ```
   Device(config)# ap tag-source-priority 2 source pnp
   ```

3. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

4. Revalidate AP tag sources. The priorities become active only after this command is run.

   Example

   ```
   Device# ap tag-sources revalidate
   ```

   Note

   If you change the priorities for Filter and PnP, and need to verify the changes, run the **revalidate** command.

The controller applies the new tag source priorities, and APs assign tags based on your configured precedence.

Create an AP filter (GUI)

Create an AP filter using GUI.

Define an AP filter to automatically apply tags to APs that match specific naming patterns.

Use this task to organize and manage access points by creating filter rules based on AP names and assigning tags for policy, site, or RF profiles.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags** > **AP** > **Filter** .
2. Click **Add** .

3. In the **Associate Tags to AP** dialog box that is displayed, enter the **Rule Name** , the **AP name regex** , and the **Priority** .
4. Optional: You can also choose the policy tag from the **Policy Tag Name** drop-down list, the site tag from the **Site Tag Name** drop-down list and the RF tag from the **RF Tag Name** drop-down list.
5. Click **Apply to Device** .

The AP filter is created. Any AP that matches the specified pattern is automatically assigned the designated tags.

Create an AP filter (CLI)

Create an AP filter using CLI.

Configure an AP filter using the CLI to apply specific policy, RF, and site tags to APs matching a name pattern.

- Identify the regular expression pattern for the AP names you want to filter.
- Determine the appropriate policy, RF, and site tag names to use.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP filter.

   Example

   ```
   Device(config)# ap filter filter-1
   ```

3. Configure the AP filter based on regular expression.

   Example

   ```
   Device(config-ap-filter)# ap name-regex testany
   ```

   For example, if you have named an AP as **ap-lab-12**, then you can configure the filter with a regular expression, such as **ap-lab-\d+** , to match the AP name.

4. Configure a policy tag for this filter.

   Example

   ```
   Device(config-ap-filter)# tag policy pol-tag1
   ```

5. Configure an RF tag for this filter.

   Example

   ```
   Device(config-ap-filter)# tag rf rf-tag1
   ```

6. Configure a site tag for this filter.

Example

```
Device(config-ap-filter)# tag site site1
```

7. Exit configuration mode to return to privileged EXEC mode.

Example

```
Device(config-ap-filter)# end
```

The AP filter is configured with the specified criteria and tag associations. APs with names matching your pattern will have the corresponding tags applied.

Configure filter priority (GUI)

Configure and set up filter priority using GUI.

Configure and manage the priority of AP filters to control tag associations on APs.

Perform this task when you need to add a new AP filter or change the priority of an existing AP filter using the GUI.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Tags** > **AP** > **Filter**.
2. Choose:
   a) To set up a new AP filter, click **Add**. In the **Associate Tags to AP** dialog box that is displayed, enter the **Rule Name**, the **AP name regex** and the **Priority**. Optionally, you can also select the **Policy Tag Name**, the **Site Tag Name** and the **RF Tag Name**. Click **Apply to Device**.
   b) To update the priority of an existing AP filter, click on the filter and in the **Edit Tags** dialog box and change the **Priority**. In case the filter is inactive, you cannot configure a priority. Click **Update and Apply to Device**.

The AP filter priority is configured or updated and applied to the specified devices.

Configure filter priority (CLI)

Configure and set up filter priority using CLI.

Configure and manage the priority of AP filters to control tag associations on APs.

Perform this task when you need to add a new AP filter or change the priority of an existing AP filter using the GUI.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure AP filter priority. Valid values range from zero to 1023. The value zero represents the highest priority.

   Example

   ```
   Device(config)# ap filter priority 10 filter-name test1
   ```

   This step is necessary to activate the filter.

3. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap)# end
   ```

The AP filter priority is configured or updated and applied to the specified devices.

Verify AP filter configuration

Verify AP Filter Configuration using commands.

These **show** commands are used to display tag sources and filters, and their priorities.

To view the tag source priorities, use the command:

```
Device# show ap tag sources

Priority Tag source
--------------------------------
0 Static
1 Filter
2 AP
3 Default
```

To view the available filters, use the command:

```
Device# show ap filter all

Filter Name             regex             Policy Tag               RF Tag
          Site Tag
-------------------------------------------------------------------------------------------
first                   abcd              pol-tag1                 rf-tag1
          site-tag1
test1                   testany
          site1
filter1                 testany
```

To view the list of active filters, use the command:

```
Device# show ap filters active

Priority   Filter Name       regex          Policy Tag               RF Tag
           Site Tag
-------------------------------------------------------------------------------------------
10         test1             testany
           site1
```

To view the source of an AP tag, use the command:

```
Device# show ap tag summary

Number of APs: 4

AP Name           AP Mac          Site Tag Name    Policy Tag Name    RF Tag
Name    Misconfigured Tag Source

   No Filter
AP58AC.78DE.9946 58ac.78de.9946 default-site-tag default-policy-tag
default-rf-tag No AP
AP0081.C4F4.1F34 0081.c4f4.1f34 default-site-tag default-policy-tag
default-rf-tag No Default
```

Location configuration

Explains location configuration for access points, covering restrictions, configuration procedures, location assignment methods, SNMP MIB integration, and verification of location settings and statistics.

This feature works in conjunction with the existing tag resolution scheme. The location is considered as a new tag source to the existing system.

A location is a network entity that

- represents a site or physical area where one or more APs are deployed
- associates a specific set of tags—policy, RF, and site tags—with those APs, and
- links each tag set to a collection of Ethernet MAC addresses corresponding to APs at that location.

Location features and usage

Locations serve as a new tag source within the tag resolution scheme, functioning similarly to static tag sources. During location configuration, you can

- configure a site or location for an AP
- assign a set of tags for the location, and
- add APs to the location.

The combination of unique tags and associated MAC addresses distinguishes each location and enables organized network management.

Restriction for location configuration

Location Configuration prerequisites.

If you configure an AP in one location, you cannot configure the same AP in another location.

Configure a location for an AP (GUI)

Configure a Location for an AP using GUI.

Create and classify a new location for an AP. Apply the appropriate type and client density settings.

Use this task when you need to add a location for AP deployment and associate location-specific policies or tags.

Before you begin

When you create local and remote sites in the basic setup workflow, the corresponding policies and tags are created automatically. Tags and policies created in the basic setup cannot be modified using the advanced workflow. Similarly, items created with the advanced workflow cannot be changed in the basic setup.

Procedure

1. Choose **Configuration** > **Wireless Setup** > **Basic**.
2. On the **Basic Wireless Setup** window, click **Add**.
3. In the **General** tab, enter a name and description for the location.
4. Set the **Location Type** as either *Local* or *Flex*.
5. Use the slider to set **Client Density** as *Low*, *Typical*, or *High*.
6. Click **Apply**.

The new location is saved and ready for assignment and policy application.

Configure a location for an AP (CLI)

Configure a Location for an AP using CLI.

Assign and configure a location for an AP using CLI commands.

Use this task to logically organize APs by location for better device management and policy assignment.

Before you begin

Confirm the AP is registered and operational.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a location for an AP.

   Example

   ```
   Device(config)# ap location name location1
   ```

   Run the **no** form of this command to remove location for an AP.

3. Configure tags for the location.

   Example

   ```
   Device(config-ap-location)# tag policy policy_tag
   ```

```
Device(config-ap-location)# tag rf rf_tag
```

```
Device(config-ap-location)# tag site site_tag
```

4. Add description to the location.

   Example

```
Device(config-ap-location)# location description
```

5. Return to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

```
Device(config-ap-location)# end
```

The AP location is set and the associated tags and a description are configured.

Add an AP to location (GUI)

Add an AP to the location using GUI.

Add an AP to a specific location using the GUI.

Use this task to associate APs with a defined location, which enables accurate AP count and location tagging in the GUI. Ensure the AP tag source is set to **location** for correct display–if needed, run the **no ap** *ap-mac* command on the controller to reset the AP tag source to default.

Before you begin

- Confirm you have the MAC address of the APs to be added.
- Optionally, prepare a CSV file with AP MAC addresses for bulk upload.

Procedure

---

1. Choose **Configuration** > **Wireless Setup** > **Basic**.
2. In the **Basic Wireless Setup** window, click **Add** to configure these options:
   - General
   - Wireless Networks
   - AP Provisioning
3. In the **AP Provisioning** tab and **Add/Select APs** section, enter the AP MAC address and click the right arrow to add the AP to the associated list. The MAC address can be either in *xx:xx:xx:xx:xx:xx*, *xx-xx-xx-xx-xx-xx*, or *xxxx.xxxx.xxxx* format.

   You can also add a CSV file from your system. Ensure that the CSV has the MAC Address column.

4. Use the search option in the **Available AP List** to select the APs from the **Selected AP** list and click the right arrow to add the AP to the associated list.
5. Click **Apply**.

The selected APs are added to the specified location, and location tagging is updated in the GUI.

Adding an Access Point to the Location (CLI)

Add an access point (AP) to a specified location on your network controller using CLI commands for efficient network management.

Use this task if you need to organize APs by site, floor, building, or area to simplify administration and monitoring.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a location for an access point.

   Example

   ```
   Device(config)# ap location name location-name
   ```

   ```
   Device(config)# ap location name location1
   ```

3. Add an access point to the location.

   Example

   ```
   Device(config-ap-location)# ap-eth-mac ap_ethernet_mac
   ```

   ```
   Device(config-ap-location)# ap-eth-mac 188b.9dbe.6eac
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-location)# end
   ```

   Alternatively, you can also press Ctrl-Z to exit global configuration mode.

> **Note**
>
> After adding an AP to a location, the AP may reset automatically to get the new configuration

The access point is successfully assigned to the specified location. The AP may reset to update its configuration.

SNMP MIB

A set of managed objects that represent logical and physical entities.

The SNMP MIB provides information on a set of managed objects that represent logical and physical entities, and relationships between them.

Table 7: MIB Objects and Notes

MIB Objects	Notes
cLApLocationName	Provides the name of the AP location.
cLApLocationPolicyTag	Provides the policy tag configured on the location.
cLApLocationSitetag	Provides the site tag configured on the location.
cLApLocationRfTag	Provides the RF tag configured on the location.
cLAssociatedApsApMac	Provides the configured APs on the location.

Verify location configuration

Verify Location Configuration using commands.

To view the summary of AP location configuration, use the command:

```
Device# show ap location summary

Location Name    Description     Policy Tag           RF Tag           Site
Tag
-------------------------------------------------------------------------------------------
first            first floor     default-policy-tag   default-rf-tag
default-site-tag
second           second floor    default-policy-tag   default-rf-tag
default-site-tag
```

To view the AP location configuration details for a specific location, use the command:

```
Device# show ap location details first

Location Name.....................: first
Location description..............: first floor
Policy tag........................: default-policy-tag
Site tag..........................: default-site-tag
RF tag............................: default-rf-tag
```

```
Configured list of APs
005b.3400.0af0
005b.3400.0bf0
```

To view the AP tag summary, use the command:

```
Device# show ap tag summary

Number of APs: 4
AP Name      AP Mac           Site Tag Name      Policy Tag Name      RF Tag
Name      Misconfigured  Tag Source
-------------------------------------------------------------------------------
Asim_5-1     005b.3400.02f0   default-site-tag   default-policy-tag
default-rf-tag   Yes            Filter
Asim_5-2     005b.3400.03f0   default-site-tag   default-policy-tag
default-rf-tag   No             Default
Asim_5-9     005b.3400.0af0   default-site-tag   default-policy-tag
default-rf-tag   No             Location
Asim_5-10    005b.3400.0bf0   default-site-tag   default-policy-tag
default-rf-tag   No             Location
```

Verify location statistics

Verify Location Statistics using commands.

To view the AP location statistics, use the command:

```
Device# show ap location stats

Location name    APs joined     Clients joined     Clients on 11a     Clients
 on 11b
-------------------------------------------------------------------------------
first             2             0                   3                  4

second            0             0                   0                  0
```

3 Wireless Management Interface

Topics:

- Wireless management interfaces
- WMI Configuration Tasks

Explains the Wireless Management Interface configuration and provides step-by-step guidance for setting up, migrating, and verifying interface settings on wireless controllers.

Wireless management interfaces

Explains Wireless Management Interface configuration, outlines step-by-step setup and migration processes, and provides verification procedures to ensure successful deployment and management on wireless controllers.

The Wireless Management Interface (WMI) is a mandatory Layer 3 interface on the controller that

- supports all communications between the controller and access points,
- enables Control And Provisioning of Wireless Access Points (CAPWAP) or inter-controller mobility messaging and tunneling traffic, and
- serves as the default interface for in-band management and connectivity to enterprise services such as AAA, syslog, and SNMP.

You can use the WMI IP address to connect to the device using SSH or Telnet. You can also access the GUI through HTTP or HTTPS by entering the WMI IP address in a browser address field.

Supported Protocols

Starting from Cisco IOS XE Release 17.6.1, the controller can use Ethernet Service Port (SP) (Management Interface VRF or GigabitEthernet 0) for specific management or control plane protocols

Supported protocols for the WMI include:

- Simple Network Management Protocol (SNMP)
- RADIUS (both for user authentication to the controller and wireless client authorization)
- TACACS+
- Syslog
- Network Time Protocol (NTP)
- SSH, Network Configuration Protocol (NETCONF), or HTTPS
- NetFlow

Best practices and restrictions for WMI

Best practices for WMI

- **IP Address Configuration**: Configure the Wireless Management Interface (WMI) with a single IP address, either IPv4 or IPv6. Alternatively, use a dual-stack configuration for flexibility in addressing.
- **IPv6 Recommendations**: Assign a static IPv6 address in WMI. Do not configure the IPv6 address using the **ipv6 auto-config** command for the WMI.
- Always use a dedicated wireless management VLAN and configure the WMI as a Switched VLAN Interface (SVI).
- If you configure the uplink port or port channel to the next-hop switch as a dot1q trunk, ensure the wireless management VLAN is allowed or tagged on the trunk.

This recommendation is applicable to all AP deployment modes (local, FlexConnect, or SDA).

The recommendation is not applicable for certain scenarios:

- The WMI is a Layer 3 port on a controller deployed in a public cloud.
- The WMI is a loopback interface for embedded wireless controller in Cisco Catalyst 9000 switches.

Restrictions

- Only one WMI is allowed on a controller.
- Use only a Layer 2 interface or anA SVI to configure the WMI.
- Do not use a Layer 3 interface for guest anchor scenarios.
- Use a Layer 3 interface for public cloud deployments only.
- Use the WMI to terminate CAPWAP traffic.
- The **ipv6 auto-config** command is not supported.

Change the WMI interface when RMI is configured

Occasionally, you may need to change the Wireless Management Interface (WMI). If Redundant Management Interface (RMI) is configured on your network, this task shows you how to change the WMI interface.

Procedure

1. Remove all RMI configurations.
2. Save the changes using the **write memory** command.
3. Reload the controller.
4. Change the WMI interface.
5. Reconfigure the RMI to use the same interface as the WMI.
6. Save the changes using the **write memory** command.
7. Reload the controller.

The WMI interface is changed, and the RMI is reconfigured to match, maintaining operational consistency.

WMI Configuration Tasks

Details essential configuration tasks for the Wireless Management Interface, including VLAN migration, sample interface configurations, step-by-step CLI setup for controllers, and verification of interface settings for optimal performance.

Migrate VLANs safely for wireless management

Safely migrate from VLAN A to VLAN B for wireless management, ensuring all devices—including those behind Workgroup Bridges (WGB)—continue to correctly receive multicast traffic.

> **Caution**
>
> Do not remove VLAN A or SVI A before creating VLAN B or SVI B and associating SVI B with WMI. This sequence is critical to prevent multicast traffic issues.

Before you begin

Procedure

1. Create VLAN B on the relevant network switches.
2. Configure SVI B (Switched Virtual Interface for VLAN B).
3. Associate SVI B with the WMI interface.
4. Verify multicast traffic is flowing correctly to all devices, including those behind WGBs.
5. Once functionality is confirmed, remove VLAN A from the network configuration.
6. Delete SVI A (Switched Virtual Interface for the old VLAN).
7. Document changes and monitor for any multicast or connectivity issues.

The VLANs are migrated, and multicast traffic is properly received by all devices, including those behind WGBs.

Sample interface configuration

Layer 3 interface configuration:

```
interface GigabitEthernet2
no switchport
ip address <ip_address> <mask>
negotiation auto
no mop enabled
no mop sysid
end
```

Layer 2 interface configuration:

```
interface GigabitEthernet2
switchport trunk allowed vlan 25,169,504
switchport mode trunk
negotiation auto
no mop enabled
no mop sysid
end
```

Configure the WMI interface of a controller (CLI)

Configure the WMI interface on a controller using the CLI.

Set up a controller, and assign a dedicated VLAN and interface for wireless management.

The examples assume the GigabitEthernet 2 interface connects to a trunk interface and that you want to configure multiple VLANs and dedicate one of them for the WMI interface.

Before you begin

- Ensure you have physical console access (for the Cisco Catalyst 9800 Series Wireless Controller Appliance) or a virtual console access (Cisco Catalyst 9800 Series Wireless Controller for Cloud).
- Determine your management VLAN, interface IP address, and credentials.

Procedure

1. Access the CLI using Video Graphics Array(VGA) or monitor console from your preferred hypervisor.
2. Terminate the configuration wizard.

```
Would you like to enter the initial configuration dialog? [yes/no]:
 no
Would you like to terminate autoinstall? [yes]:
 yes
```

3. Enter the global configuration mode and configure the login credentials.

```
Device# conf t
Enter configuration commands, one per line.  End with CNTL/Z.
Device(config)# username <name> privilege 15 password <yourpwd>
```

4. Set a hostname.

```
Device(config)# hostname C9800
```

5. Configure the VLAN for the wireless management interface.

```
Device(config)# vlan 201
Device(config-vlan)# name wireless_management
```

6. Configure the Layer 3 SVI for wireless management interface.

```
Device(config)# int vlan 201
Device(config-if)# description wireless-management-interface
Device(config-if)# ip address 172.16.201.21 255.255.255.192
Device(config-if)# no shutdown
```

7. Configure an interface as trunk and allow the wireless management VLAN.

```
Device(config-if)# interface GigabitEthernet2
Device(config-if)# switchport mode trunk
Device(config-if)# switchport trunk allowed vlan 201,210,211
Device(config-if)# shut
```

```
Device(config-if)# no shut
```

> **Note**
>
> VLANs 210 and 211 are added to the trunk to carry client traffic.

8. Configure a default route or a more specific route to reach the device.

```
Device(config-if)# ip route 0.0.0.0 0.0.0.0 172.16.201.1
```

The controller is configured with a dedicated wireless management VLAN and SVI. You can access the device using SSH, telnet, or GUI. You can use the Cisco Catalyst Center or Cisco Prime Infrastructure to continue with the Day 0 configuration.

Verify WMI Settings

Verify Wireless Management Interface Settings using CLI.

Verify if the Layer 3 interface is configured correctly.

```
Device# show run int vlan 201

Building configuration...

Current configuration : 128 bytes
!
interface Vlan201
 description wireless-management-interface
 ip address 172.16.201.21 255.255.255.0
 no mop enabled
 no mop sysid
end
```

Verify if the wireless management VLAN is active on the uplink to the network. In this case, the uplink is a trunk interface, so the VLAN needs to be active and forwarding state.

```
Device# show interfaces trunk

Port        Mode             Encapsulation  Status        Native vlan
Gi2         on               802.1q         trunking      1
.....
Port        Vlans allowed on trunk
Gi2         201,210-211
.....
Port        Vlans allowed and active in management domain
Gi2         201,210-211
....
Port        Vlans in spanning tree forwarding state and not pruned
Gi2         201,210-211
....
```

Verify if the wireless management interface is up.

```
Device# show ip int brief | i Vlan201
Vlan201   172.16.201.21  YES NVRAM  up  up
```

Verify if the selected interface has been configured as wireless management.

```
Device# show wireless interface summary

Wireless Interface Summary

Interface Name Interface Type VLAN ID IP Address     IP Netmask   NAT-IP Address
 MAC Address
-----------------------------------------------------------------------------------------
Vlan201       Management       201   172.16.201.21  255.255.255.0  0.0.0.0
   001e.e51c.a7ff
```

4 Configure Network Address Translation for Wireless Management IP

Topics:

- Network address translation

Guides the configuration of Network Address Translation for wireless management interfaces and outlines Control and Provisioning of Wireless Access Points discovery settings for public and private IP environments.

Network address translation

Describes Network Address Translation (NAT) and its security details.

Network Address Translation (NAT) is a networking mechanism that

- enables private IP networks that use non-registered IP addresses to connect to the Internet
- translates private addresses from the internal network into public addresses before forwarding packets onto another network, and
- provides security by effectively hiding the private network details through advertising only few addresses for the entire internal network.

NAT deployment with Cisco Catalyst 9800 wireless controller

If you want to deploy your Cisco Catalyst 9800 Wireless Controller on a private network and make it reachable from internet, you need to have the controller behind a router, firewall, or other gateway device that uses one-to-one mapping Network Address Translation (NAT).

To do so, perform these steps:

- Configure the NAT device with 1:1 static mapping of the Wireless Management interface IP address (private IP) to a unique external (public) IP address configured on the NAT device.
- Enable the NAT feature on the Wireless Controller and specify its external public IP address. This public IP is used in the discovery responses to APs, so that the APs can then send CAPWAP packets to the right destination.
- Make sure that the external APs discover the public IP of the controller using DHCP, DNS, or PnP.

Note

Certain ISP routers performing NAT may assign the same public source PORT to different APs. This results in the WLC receiving CAPWAP traffic from same IP:PORT but from different APs. The controller is unable to differentiate the packets are from differnent APs, even if packet A is for DATA and Packet B is for CTRL. The controller does not support CAPWAP connections from different APs behind NAT using same SRC IP:PORT.

Note

You need not enable NAT if the Cisco Catalyst 9800 Wireless Controller is deployed with a public address. Instead you will need to configure the public IP directly on the Wireless Management Interface (WMI).

The IPv6 addresses that are not supported are:

- IPv6 Documentation addresses - 2001:db8::/32
- IPv6 Site Local addresses - fec0::/10
- IPv6 Link Local addresses - fe80::/10
- IPv6 Loopback addresses - ::1

- IPv6 Multicast addresses - FF00::/8

CAPWAP discovery

Describes CAPWAP discovery and its environment details.

CAPWAP discovery is a network mechanism that

- enables lightweight access points to discover wireless controllers using CAPWAP discovery mechanisms
- facilitates CAPWAP join requests from access points to controllers, and
- allows controllers to send CAPWAP join responses to access points for joining the controller.

NAT environment response methods

If the wireless controller is behind a NAT device, the controller responds to the discovery response in the following ways:

- Using the public IP
- Using the private IP
- Using public and private IP

The Public IP needs to be mapped to the controller's Private IP using static 1:1 NAT configuration on the router or firewall performing the NAT translation.

If your wireless controller manages only Access Points reachable through the public internet (external APs), you need to configure the controller so it responds with only the Public IP in the discovery response.

If your wireless controller manages both internal and external APs, you need to configure the controller so it responds with both Public and Private IPs in the discovery response.

> **Note**
>
> In NAT deployments, the APs running internally and externally must use different AP join profiles with CAPWAP Discovery Private and Public enabled separately. This behaviour was introduced from the 17.9.5 release and applies to APs upgraded to Cisco IOS XE 17.9.5, 17.9.6, 17.9.m (m>=5), 17.12.n (n>=1) and later releases.

Configure wireless management interface with a NAT public IP (CLI)

Configure wireless management interface with a NAT public IP using commands.

Enable the controller to use a public NAT IP address for wireless management interface communication.

Configure the controller to use the public NAT IP (this is the public IP that has been configured on the NAT device to statically map 1:1 the WMI's private IP address). This configuration allows the wireless management interface to operate in NAT environments where public IP access is required.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Define the management interface.

Example

```
Device(config)# wireless management interface interface-type interface-number
```

Example

```
Device(config)# wireless management interface vlan 20
```

- *interface-type*: Refers to the VLAN, Gigabit, or loopback types.
- *interface-number*: Is the interface number.

3. Define the external NAT or Public IP.

Example

```
Device(config-mgmt-interface)# public-ip external-public-ip
```

Example

```
Device(config-mgmt-interface)# public-ip 2.2.2.2
```

4. Return to privileged EXEC mode.

Example

```
Device(config-mgmt-interface)# end
```

The wireless management interface is now configured with the NAT public IP and can communicate through the NAT device using the specified public IP address mapping.

CAPWAP discovery IP response configuration

Describes the configuration of CAPWAP discovery to respond with specific IP address types using CLI commands.

CAPWAP discovery IP response configuration is a wireless controller setting that controls which IP addresses the controller includes in CAPWAP discovery responses to access points.

CAPWAP discovery response behavior

The controller's IP response behavior in CAPWAP discovery varies based on configuration:

- **Default behavior**: If the wireless management interface is configured with a public IP, the controller responds with both Public and Private IP in the CAPWAP discovery response.
- **Configurable setting**: The setting to determine the IP (private or public) to include in the discovery response is available in the AP Join profile.

Configure the Controller to Respond only with a Public IP (CLI)

Configure the Controller to respond only with a Public IP using commands.

Enable APs to join the controller over public IP only by preventing responses with internal IP addresses.

Configure the Controller to respond only with a Public IP using commands when you need to restrict AP discovery to public interfaces only.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   Example

   ```
   Device(config)# ap profile xyz-ap-profile
   ```

3. Instruct the controller to not respond with the internal IP.

   Example

   ```
   Device(config-ap-profile)# no capwap-discovery private
   ```

   Enables AP to join the controller over Public IP only.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

The controller is now configured to respond only with public IP addresses, ensuring that APs can only join using the public interface.

Configure the controller to respond only with a private IP (CLI)

Configure the controller to respond only with a private IP using commands.

Configure the controller to respond only with private IP addresses during CAPWAP discovery.

This configuration ensures that access points join the controller using private IP addresses instead of public IP addresses, which is useful in network environments where direct public IP communication should be restricted.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   Example

   ```
   Device(config)# ap profile xyz-ap-profile
   ```

3. Instruct the controller to not respond with the public IP.

   Example

   ```
   Device(config-ap-profile)# no capwap-discovery public
   ```

   Enable AP to join the controller over private IP only.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

The controller is now configured to respond only with private IP addresses during CAPWAP discovery, ensuring APs join using private network connections.

Verify NAT settings

Provides commands for verifying NAT settings and AP join profile configurations.

Verify NAT Settings using commands.

```
Device# show wireless interface summary

Wireless Interface Summary

Interface Name Interface Type VLAN ID IP Address     IP Netmask     NAT-IP
Address   MAC Address
-------------------------------------------------------------------------------------
Vlan20         Management     20      10.58.20.25    255.255.255.0  2.2.2.2
  001e.4963.1cff
```

To verify the settings in the AP join profile, use this command

```
Device# show run | b ap profile

ap profile default-ap-profile
 no capwap-discovery private
 description "default ap profile"
...
```

5 Hardware Features

Topics:

- BIOS Protection on the Controller
- USB disablement

Outlines hardware security and management capabilities for controllers, detailing BIOS protection and upgrade procedures, as well as USB disablement via CLI to enhance device integrity and reduce vulnerabilities.

BIOS Protection on the Controller

BIOS Protection and how it works.

BIOS Protection enables you to protect and securely update BIOS flash for Intel-based platforms. If BIOS Protection is not used, the flash utility that stores the BIOS for an Intel platform is not write-protected. As a result, when BIOS updates are applied, malicious code also makes its way through.

By default, BIOS Protection works by bundling the flash containing the BIOS image, and by accepting updates only through the BIOS capsules that enable writing on the BIOS Flash.

BIOS or ROMMON Upgrade with BIOS Protection

Configure BIOS or ROMMON Upgrade with BIOS Protection.

To upgrade BIOS or ROMMON use the BIOS Protection feature as follows:

1. The new BIOS image capsule bundled together with the ROMMON binary is inserted into the media of the Cisco device by the ROMMON upgrade scripts.
2. The Cisco device is then reset for the new BIOS/ROMMON upgrade to take place.
3. On reset, the original BIOS detects the updated capsule and determines if the updated BIOS is available.
4. The original BIOS then verifies the digital signature of the BIOS capsule. If the signature is valid, the original BIOS will remove write-protection from the flash utility and update the SPI flash with the new BIOS image. If the BIOS capsule is invalid, the SPI flash is not updated.
5. After the new BIOS/ROMMON image is written to the SPI flash, the required regions of the SPI flash are once again write-protected.
6. After the card is reset, the updated BIOS is rebooted.
7. The capsule is deleted by BIOS.

Upgrading BIOS

Upgrade BIOS using commands.

Procedure

Use the **upgrade rom-monitor filename** command to update the BIOS capsule.

Example

```
upgrade rom-monitor filename bootflash:capsule.pkg <slot>
```

Example

The following example shows you how to verify a BIOS Protection upgrade:

```
Device# upgrade rom-monitor filename bootflash:qwlc-rommon-capsule-p106.pkg
all
Verifying the code signature of the ROMMON package...
Chassis model AIR-CT5540-K9 has a single rom-monitor.

Upgrade rom-monitor
```

```
Target copying rom-monitor image file

Secure update of the ROMMON image will occur after a reload.

8388608+0 records in
8388608+0 records out

131072 bytes (131 kB, 128 KiB) copied, 2.43394 s, 53.9 kB/s
ROMMON upgrade complete.
To make the new ROMMON permanent, you must restart the RP.
Device#reload
```

USB disablement

Explains how to disable and reenable USB ports using platform commands, notes the absence of system messages when USB devices are inserted while disabled, and clarifies that Bluetooth dongles are not affected by these commands.

USB ports are hardware interfaces on standalone or stacked devices that:

- can be disabled together using the `platform usb disable` command
- can be reenabled using the `no platform usb disable` command, and
- do not generate system messages when a USB device is inserted while the ports are disabled.

The `platform usb disable` command disables USB ports on the device, but it does not disable Bluetooth dongles connected to USB ports.

Disable USB (CLI)

Disable all USB ports on a standalone or stacked device using CLI commands to prevent the use of USB devices for security purposes.

Disable all USB ports on a standalone or stacked device.

Use this task when you want to prevent USB devices from being used on the device. When USB ports are disabled, the device does not generate system messages if a USB device is inserted.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Disable all the USB ports on the device.

Example

```
Device(config)# [no] platform usb disable
```

Use the **no platform usb disable** command to reenable the USB ports.

All USB ports on the device are disabled. The device will not recognize or generate system messages for connected USB peripherals.

6 Smart Licensing Using Policy

Topics:

- Smart Licensing Using Policy

Smart Licensing Using Policy

Smart Licensing Using Policy is a Cisco licensing system that is automatically enabled on controllers and upgrades, ensuring that your Smart Account and Virtual Account in Cisco Smart Software Manager are ready for policy-driven license management by default.

The Smart Licensing Using Policy feature is automatically enabled on the controller. This is also the case when you upgrade to this release. By default, your Smart Account and Virtual Account in Cisco Smart Software Manager (CSSM) are enabled for Smart Licensing Using Policy. For more information, see Smart Licensing Using Policy. To use Smart Licensing, you must first set up a Smart Account on Cisco License Central. For a more detailed overview on Cisco Licensing, visit Licensing Hub.

7 Management over Wireless

Topics:

- Management over wireless

Chapter wrapper for the map in vEWLC config guide.

Management over wireless

Management over Wireless details.

Management over wireless is a feature that allows you to monitor and configure the controller using client devices connected over Wi-Fi. This feature is helpful in situations where a wired connection is not available. The feature:

- allows you to monitor and configure the controller using client devices connected through Wi-Fi,
- is helpful in situations where a wired connection is not available, and
- is usually disabled by default for security reasons.

> **Attention**
>
> By default, the feature is disabled for security reasons. If disabled, the controller blocks any management access attempts from its connected wireless clients. This helps prevent someone connected over Wi-Fi from directly managing the controller they are using.

However, keeping this feature disabled does not block management access from wireless clients that are connected to other controllers in the network. To enforce stricter access control across all wireless clients, use Access Control Lists (ACLs) or similar mechanisms, based on VLANs or IP ranges.

Restrictions on management over wireless

Management over wireless comes with important restrictions regarding EWC and feature disablement.

- The feature does not work for Embedded Wireless Controller (EWC).
- By default, this feature is disabled for security reasons.

Configure management of controller over wireless network (GUI)

Enable Management over Wireless on the controller using GUI.

Enable management of the controller over wireless clients. This allows you to monitor and configure the controller using client devices connected over the wireless network.

Procedure

1. Choose **Configuration > Wireless > Wireless Global**.
2. Check the **Management via Wireless** check box.
3. Click **Apply**.

You can now manage the controller using client devices connected over the wireless networks.

Configure management of controller over wireless network (CLI)

Guides you through enabling or disabling controller management over the wireless network using the CLI, allowing monitoring and configuration from wireless client devices.

Enable management of the controller over wireless clients. This allows you to monitor and configure the controller using client devices connected over the wireless network.

Procedure

1. Enable management over wireless.

   Example

   ```
   Device(config)# wireless mgmt-via-wireless
   ```

   Use the **no** form of this command to disable management over wireless.

You can now manage the controller using client devices connected over the wireless network.

8 Boot Integrity Visibility

Topics:

- Boot integrity visibility

Boot integrity visibility

Boot integrity visibility allows the Cisco platform identity and software integrity information to be visible.

Boot integrity visibility is a security feature that

- makes Cisco platform identity and software integrity information visible,
- enables verification of the boot process through checksum evaluation, and
- assists in ensuring that only trusted code is booted on the platform.

Platform identity provides the platform's manufacturing installed identity. Software integrity exposes boot integrity measurements used to assess if trusted code has been booted.

During the boot process, the software creates a checksum record of each bootloader stage, which can be compared against a Cisco-certified record to verify the authenticity of the software image. Mismatched checksum values might indicate a non-Cisco certified or altered software image.

Feature history for boot integrity visibility

Boot Integrity Visibility feature history.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 8: Feature History for Boot Integrity Visibility

Release	Feature Information
Cisco IOS XE 17.4.1	This feature was introduced.

Verify software image and hardware

Verify the integrity of the device's software image and hardware by retrieving and reviewing the checksum records created during switch bootup.

This task describes how to retrieve the checksum record that was created during a switch bootup.

Enter the following commands in privileged EXEC mode. The messages `% Error retrieving SUDI certificate` and `% Error retrieving integrity data` signify a real CLI failure.

> **Note**
>
> On executing the following commands, you might see the message `% Please Try After a Few Seconds` displayed on the CLI. This does not indicate a CLI failure, but indicates setting up of underlying infrastructure required to get the required output. We recommend waiting for a few minutes and then try the command again.

Procedure

1. View the checksum record for a specific SUDI

Example

```
Device# show platform sudi certificate sign nonce 123
```

Displays checksum record for the specific SUDI.

- (Optional) **sign** - Shows signature
- (Optional) **nonce** *nonce* - Enter a nonce value

2. View the checksum record for boot stages

Example

```
Device# show platform integrity sign nonce 123
```

Displays checksum record for boot stages.

- (Optional) **sign** - Shows signature
- (Optional) **nonce** *nonce* - Enter a nonce value

You obtain the checksum records for the device's software image and hardware, confirming their integrity or identifying any issues.

Verify platform identity and software integrity

Verify Platform Identity and Software Integrity.

Verify platform identity

The following example displays the Secure Unique Device Identity (SUDI) chain in PEM format. Each SUDI includes the Product ID (PID) and serial number (SN), so you can uniquely identify each device on a large network.

The first certificate is the Cisco Root CA 2048, and the second is the Cisco subordinate CA (ACT2 SUDI CA). You can verify both certificates by comparing them with those published on https://www.cisco.com/security/pki/. The third certificate is the SUDI certificate.

Important

The CLI outputs in this document are examples for your reference. Your output may differ depending on the configuration of your device.

```
Device# show platform sudi certificate sign nonce 123

-----END CERTIFICATE-----

Signature version: 1
Signature:
```

The optional RSA 2048 signature covers the three certificates, the signature version, and the user-provided nonce.

```
RSA PKCS#1v1.5 Sign {<Nonce (UINT64)> || <Signature Version (UINT32)> || <Cisco
 Root CA 2048 cert (DER)> ||
<Cisco subordinate CA (DER)> || <SUDI certificate (DER)>}
```

Cisco management solutions interpret this output. You can also use a simple script with OpenSSL commands to display platform identity and verify the signature, which helps confirm the Cisco unique device identity..

```
[linux-host:~]openssl x509 -in sudi_id.pem -subject -noout
subject= /serialNumber=PID:C9600-SUP-1
SN:CAT2239L06B/CN=C9600-SUP-1-70b3171eaa00
```

Verify software integrity

The following example shows the checksum record for the boot stages. The hash measurements appear for each of the three software stages when they boot in sequence. Compare these hashes to the Cisco-provided reference values.

Signing the output ensures it is genuine and unaltered. Provide a nonce to protect against replay attacks.

Note

Boot integrity hashes are not MD5 hashes. For example, if you run **verify /md5 cat9k_iosxe.16.10.01.SPA.bin** command for the bundle file, the hash will not match.

The following is a sample output of the **show platform integrity sign nonce 123** command. This output includes measurements of each installed package file.

```
Device# show platform integrity sign nonce 123
Platform: C9800-L-F-K9
Boot 0 Version: R04.1173930452019-06-11
Boot 0 Hash: A6C92C44976FC77DD42234444FFD87798FB9036A2762FAA4999A190A0258B18C
Boot Loader Version: 16.12(1r)

```

Note

Only OS and package hashes are supported.

9 SUDI99 Certificate Support

Topics:

- SUDI certificates

SUDI certificates

Explains what SUDI certificates are, their role in secure authentication, and the enhancements brought by SUDI99 certificate support.

A Secure Unique Device Identity (SUDI) is a device credential that

- provides device-specific authentication during secure connection handshakes
- is provisioned in a secure hardware chip during manufacturing, and
- supports multiple certificates for interoperability with diverse network environments.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 9: Feature history for SUDI99 certificate support

Feature Name	Release Information	Feature Description
SUDI99 certificate support	Cisco IOS XE Dublin 17.7.1	This feature allows a network administrator to use SUDI99 certificates for authentication during secure connection handshakes enhancing security through device-specific credentials

SUDI certificates validate device identity, ensuring only genuine devices connect to Cisco networks. They play a crucial role in maintaining the security of network infrastructure.

Note

Some existing SUDI certificates, such as those used in controller and AP platforms, are set to expire in May 2029. To ensure continued secure authentication, the SUDI refresh program migrates SW-SUDI SHA1 certificates to the new SUDI99 certificates with extended validity.

Software selection for SUDI trustpoint certificates

Cisco IOS XE software supports two slots for initializing SUDI certificates from the secure hardware chip. This SUDI99 migration change will rearrange certificate-to-trustpoint mapping as follows:

Table 10: Existing software selection for SUDI trustpoint certificates

Trustpoint Name	Software Selection Among Programmed Certificate Chains
CISCO_IDEVID_SUDI	CMCA2 SHA2 SUDI (SHA2-2037)
CISCO_IDEVID_SUDI_LEGACY	CMCA SHA1 SUDI

Table 11: New software selection for SUDI trustpoint certificates

Trustpoint Name	Software Selection Among Programmed Certificate Chains
CISCO_IDEVID_SUDI	CMCA-III SHA2 SUDI99
CISCO_IDEVID_SUDI_LEGACY	CMCA2 SHA2 SUDI (SHA2-2037)

> **Caution**
>
> Avoid using expired certificates for device authentication to prevent service disruption.

SUDI99 certificate and software support

The table lists the SUDI99 certificate and software support:

Table 12: SUDI99 certificate and software support

Cisco Catalyst 9800 Controllers	SUDI99 Certificate Support	Software Support for SUDI99 Migration
Cisco Catalyst 9800-CL Wireless Controller for Cloud	Not supported.	–
Cisco Catalyst 9800 Series Wireless Controllers • 9800-40 • 9800-80 • 9800-L	Supported	Yes. From Cisco IOS XE Cupertino 17.7.1.
Cisco Embedded Wireless Controller on Catalyst Access Points. • 9105AXI • 9115AXI • 9115AXE • 9117AXI • 9120AXI • 9120AXE • 9120AXP • 9130AXI • 9130AXE	Supported	Yes. From Cisco IOS XE Cupertino 17.7.1.

Cisco Catalyst 9800 Controllers	SUDI99 Certificate Support	Software Support for SUDI99 Migration
Cisco Embedded Wireless Controller on Catalyst Switches • 9300 Series • 9400 Series • 9500 Series • 9500H Series	Not supported.	–

Backward compatibility

Backward compatibility refers to the Cisco Catalyst 9800 Series Wireless Controllers maintaining their functionality with legacy systems by using existing certificates for devices that cannot validate SUDI99.

- If your device (AP or controller) cannot validate the SUDI99 certificate, the controller switches to an older certificate (SHA2-2037) for the connection.
- For NMSP-TLS connections with Cisco CMX, the client certificate is not validated in default security mode. However, in FIPS mode, Cisco CMX validates the controller certificate.
- In FIPS mode, install the new SUDI CA certificates on the earlier version of Cisco CMX, or upgrade to the latest version.

Important

Some applications, such as HTTPS, RADSEC, and WebAuth, do not use the SUDI certificate as their default trustpoint. However, you can configure them to use the SUDI trustpoint explicitly. The SUDI refresh program alters the certificate selection for such services. However, there is no functional impact.

Restrictions of SUDI99 certificates

- Incorrectly programmed SUDI99 certificates are rejected during trustpoint initialization at bootup, reverting to previous mappings.
- We recommend ensuring accurate certificate programming to avoid service disruptions during migration.
- User can verify the SUDI certificate status using the **show platform sudi pki** command.

Disable SUDI99 migration (GUI)

Disable SUDI99 migration using GUI.

SHA1 SUDI certificates on hardware controllers have an imminent expiry date and devices using expired certificates face disruption in service.

Controllers come programmed with newer certificates in their secure hardware chip, ensuring a smooth migration to the latest SUDI99 certificate issued by CMCA-III authority. These certificates are enabled by default and are valid till December 2099.

Follow this procedure if you wish to continue using the current certificate:

Procedure

1. Choose **Configuration** > **Security** > **PKI Management** > **Trustpoints**, go to the **SUDI Status** section.
2. Disable the **Cisco Manufacturing CA III certificate** to continue using the older certificate that is mapped to an existing Trustpoint.
3. Click **Apply**.

What to do next

Reload the device for the configuration to take effect.

Disable SUDI99 migration (CLI)

Disable SUDI99 migration using CLI.

The SUDI99 certificate is set as the default trustpoint in supported hardware units.

Follow the below steps to disable it:

Procedure

1. Form the high availability pair in HA deployments.

   Example

   ```
   no platform sudi cmca3
   ```

2. Save the configuration.
3. Reload the controller to disable the SUDI certificate and fall back to the older trustpoint certificate.

What to do next

To check the certificate validation status, use the **show platform sudi pki** command.

10 Link Aggregation Group

Topics:

- Link aggregation group
- Port aggregation protocol
- Multi-LAG
- Configure link aggregation group

Link aggregation group

Explains how link aggregation groups (LAGs) combine controller ports to improve redundancy, simplify configuration, and support load balancing.

A link aggregation group is a port-channeling technology that

- combines all of a controller's distribution system ports into a single 802.3ad port channel
- reduces the number of IP addresses required for port configuration, and
- dynamically manages port redundancy and load-balances AP transparently to the corresponding user.

LAG simplifies controller configuration by eliminating the need to configure ports for each interface. If any controller port fails, traffic migrates automatically to other functioning ports. As long as at least one controller port is functioning, the system continues to operate. Wireless clients can continue to send and receive data, and APs remain connected to the network.

The wireless management VLAN can be assigned to only one port channel.

LACP is supported on a standalone controller from the Cisco IOS XE Gibraltar 16.12.x release. LACP is supported on an SSO pair from Cisco IOS XE Amsterdam 17.1.1s and later.

If a dual MAC entry is generated in the switchport MAC table when using ISE licensing enforcement, it may consume two licenses for a single AP. To avoid this issue when only one port is used, choose wired0.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 13: Feature history for link aggregation group

Feature Name	Release Information	Feature Description
Link aggregation group	Cisco IOS XE Amsterdam 17.2.1	This feature provides flexibility for connecting the controller to multiple switching infrastructures. Using multi-LAG, you can connect multiple uplinks from the controller to separate uplink switches.

Link aggregation control protocol

LACP is a part of an IEEE specification (802.3ad) that allows you to bundle several physical ports together to form a single logical channel.

A link aggregation control protocol (LACP) is a network protocol that:

- Bundles several physical ports together to form a single logical channel.
- Negotiates automatic bundling by sending LACP packets to a peer.
- Maintains network operation by dynamically grouping and rerouting traffic into a single logical link (channel or aggregate port) if any ports fail.

Link Aggregation Control Protocol (LACP) is a part of the IEEE 802.3ad specification. If any port in the bundle fails, traffic shifts to the remaining working ports, ensuring uninterrupted connectivity. APs and wireless clients can continue to send and receive data.

LACP configuration options for LAG

LACP configuration options for LAG.

To configure LAG using LACP, create multiple port-channel interfaces. Then, add each interface to the corresponding port bundle. Configure LACP on the uplink switch. This configuration allows the LACP bundle to become active.

Steps to configure LAG using LACP:

- Create a port-channel interface
- Add interface to the port-channel
- Add VLAN to LAG
- Add interface to the port-channel

Port aggregation protocol

Explains how port aggregation protocols automate and manage the bundling of Ethernet ports to increase throughput and provide redundancy.

A port aggregation protocol is a Cisco-proprietary network protocol that facilitates the automatic combination of EtherChannels by exchanging PAgP packets between Ethernet ports. PAgP packets are sent between Fast EtherChannel-capable ports in order to form a channel.

When any of the active ports fail, a standby port becomes active. By using PAgP, the controller learns the identity of partners that support PAgP and the capabilities of each port.

PAgP then dynamically groups similarly configured ports (on a single device in a stack) into a single logical link (channel or aggregate port). Similarly configured ports are grouped based on hardware, administrative, and port parameter constraints.

PAgP LAG configuration attributes

PAgP LAG configuration attribute details.

To configure LAG using PAgP, create multiple port-channel interfaces and add them to the corresponding port bundle. Configure PAgP on the uplink switch so that the PAgP bundle can become active.

Follow these steps to configure LAG using PAgP:

- Create a port-channel interface
- Add interface to the port-channel

Port channel interface number

Port channel interface number details.

A port channel interface number is a configuration identifier that uniquely distinguishes a port channel logical interface. It defines allowable ranges and limits depending on the controller model.

From Cisco IOS XE Bengaluru 17.5.1 onwards, port channel interface numbers from one to 64 are supported, with model-dependent limits on the following Cisco Catalyst 9800 Series Wireless Controllers:

- Cisco Catalyst 9800-CL Wireless Controller for Cloud: The available range on the CLI is one to 64. The maximum supported port channel interfaces are 64.
- Cisco Catalyst 9800-L Wireless Controller: The available range on the CLI is one to 64. The maximum supported port channel interfaces are 14.
- Cisco Catalyst 9800-40 Wireless Controller: The available range on the CLI is one to 64. The maximum supported port channel interfaces are 16.
- Cisco Catalyst 9800-80 Wireless Controller: The available range on the CLI is one to 64. The maximum supported port channel interfaces are 64.

For example on the Cisco Catalyst 9800-L Wireless Controller, port-channel interface numbers can be anywhere between one and 64, provided that no more than 14 port-channel interfaces are configured.

If 16 port-channel interfaces have been configured on the Cisco Catalyst 9800-40 Wireless Controller, and the system has reached its limit, an error message appears when you attempt to configure a 17th port-channel interface:

```
Device(config)#
                Dec 15 08:58:22.209 CST: %ETC-5-CANNOT_ALLOCATE_AGGREGATOR:
Aggregator limit reached, cannot allocate aggregator for group 17
```

When you downgrade from Cisco IOS XE Bengaluru 17.5.1 to an earlier version, if port channels are configured beyond the supported range of the earlier version, errors appear upon startup. The unsupported port channels disappear after the downgrade is complete.

```
interface Port-channel29
                ^% Invalid input detected at '^' marker.
                interface Port-channel35
                ^% Invalid input detected at '^' marker.
```

Note that the HA pairing remains intact after downgrade.

Flow control

A flow control mechanism is a network protocol feature that:

- Enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end.
- Uses pause frames for signaling congestion and allows congested nodes to pause traffic from other nodes to prevent packet loss.

Flow control is enabled by default for both bay0 and bay1 ports as a first-day behavior. If you see overruns on a Cisco Catalyst 9800-L Wireless Controller due to burst traffic, enable flow control on the uplink switch. This change helps the uplink switch honor the flow control settings enabled on the controller.

Although the show command might indicate that flow control is off or unsupported in the controller's CLI, the actual default behavior is that flow control is enabled. For more information, check https://bst.cloudapps.cisco.com/bugsearch/bug/CSCwk52366.

LAG configuration in ON mode

LAG configuration in ON mode.

To configure LAG in ON mode, create multiple port-channel interfaces and add them to the corresponding port bundle. Configure LACP on the uplink switch so that the LACP bundle becomes active.

- Configure LAG in ON mode (CLI) on page 184

Multi-LAG

Explains how Multi-LAGs provide high availability and increased bandwidth by aggregating multiple network links across different devices.

Multichassis link aggregation group

Multichassis link aggregation group provides flexibility in connecting the controller to a switch's infrastructure.

A multichassis link aggregation group (multi-LAG) is a switch interconnection technology that:

- Connects multiple controller uplinks to separate uplink switches for redundancy and load balancing.
- Supports VLAN-based traffic splitting when connected to a multiswitch topology.
- Provides the ability to distribute traffic on different uplinks, based on VLANs. For example, guest traffic can be completely isolated to a different switch or network from the enterprise network. You cannot configure the same VLAN on both uplinks.

Starting with Cisco IOS XE Amsterdam 17.2.1, the multichassis link aggregation group (multi-LAG) feature, which provides flexibility in connecting the controller to a switch's infrastructure, is supported.

You can connect a LAG to a single switch. However, different VLANs is connected to different LAGs. The redundancy port is connected to the same distribution switch as the uplinks or directly connected in a back-to-back configuration.

Multi-LAG is supported in LAG ON mode, LACP, and PAgP modes.

Prerequisites for Multi-LAG

Prerequisites for Multi-LAG.

To ensure optimal performance and avoid configuration conflicts:

- Connect each LAG to a single switch.
- Assign different VLANs to different LAGs.

Restrictions for Multi-LAG

Multi-LAG restrictions.

- Automatic failover from the primary LAG to the secondary LAG is not supported if the primary LAG fails.
- The interface on the controller does not come up when you shut or unshut the associated switch port.

> **Note**
>
> This restrictions is specific to Cisco Catalyst 9800-CL Cloud Wireless Controllers deployed in KVM environments using SR-IOV.

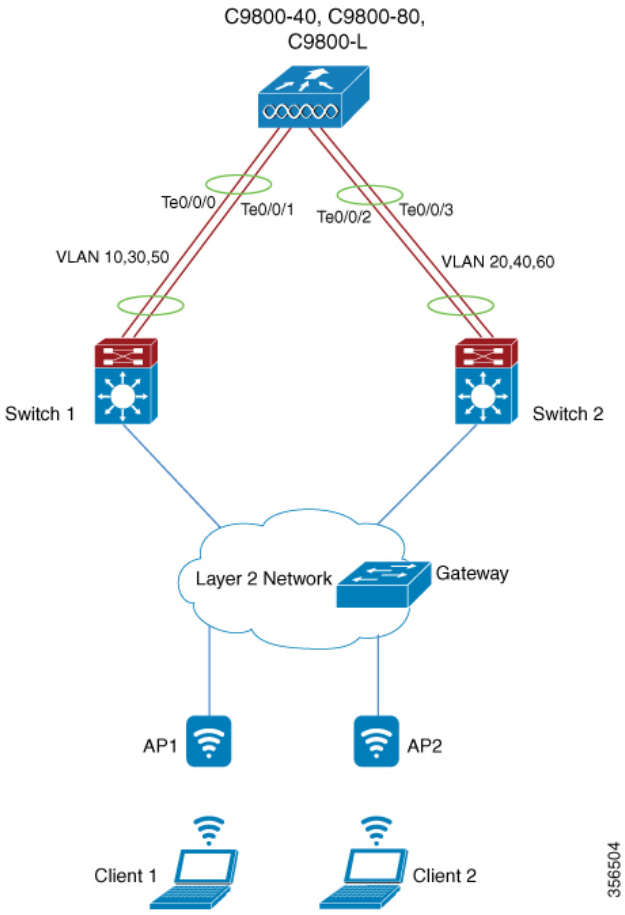
Supported topologies

Supported topologies details.

Supported topologies are network deployment configurations. They define how Cisco Catalyst 9800 series controllers connect with the network through their available ports and set limitations regarding mixing port types and minimum group sizes for link aggregation.

The Cisco Catalyst 9800-80 Wireless Controller has eight ports, while the Cisco Catalyst 9800-40 and Cisco Catalyst 9800-L wireless controllers have four ports each. Multi-LAGs can only include ports with matching capabilities, such as 2.5 G with 2.5 G, or 10 G with 10 G ports. You cannot include both a 2.5 G port and a 10 G port in a port channel group. Each group must have a minimum of two ports in one LAG.

Figure 2: Single Controller with Multi-LAG



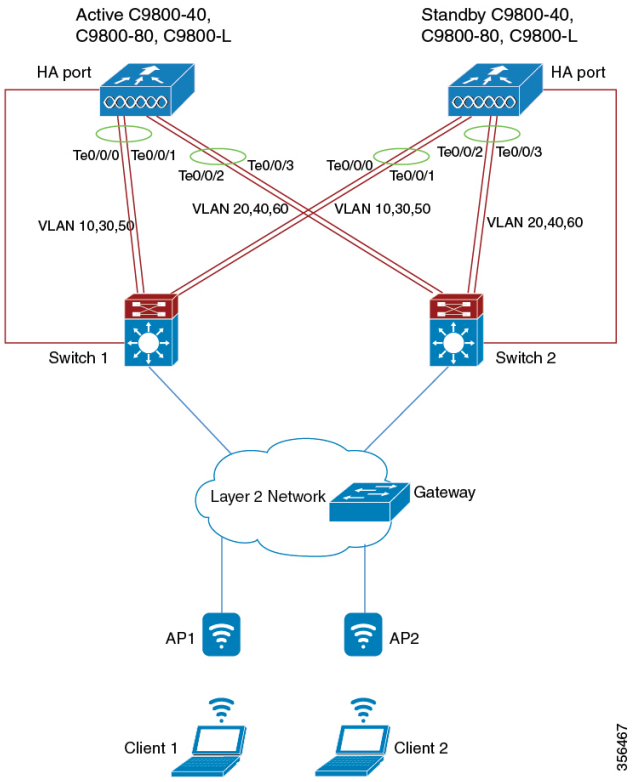


Figure 3: SSO Pair with Multi-LAG

Configure link aggregation group

Configure a link aggregation group to increase bandwidth and provide redundancy by combining multiple physical links.

Configure a port channel interface (GUI)

Configure a port channel interface using GUI.

Add and configure a logical port channel interface using the device GUI.

Procedure

1. Choose **Configuration** > **Interface** > **Logical**.
2. Click the **Port Channel** tab to configure the Port Channel interface.

   The **Port Channel** tab lists all the logical port-channel interfaces on the device.
3. Click **Add** to create a new logical port channel interface.

   The **Add Port Channel Interface** window is displayed.
4. In the **Add Port Channel Interface** window, complete the following procedure:
   a) In the **Port Channel Number** field, enter the port channel number. The valid values are between one to 64.
   b) In the **Description** field, enter the port channel description.
   c) Click the **Admin Status** toggle button to set the admin status as *UP* or *DOWN*.
   d) Click the **Enable Layer 3 Address** toggle button to enable the Layer 3 address.
   e) In the Port Members section, select the port members from the **Available** list box and add them to the **Associated** list.
   f) Choose a switch mode for the interface from the **Switchport Mode** drop-down list.

- If you select **access** as the switch mode, enter the access VLAN ID in the **Access VLAN** field.
- If you select **trunk** as the switch mode, enter the VLAN IDs that you want to assign as trunk links. To allow all VLAN IDs as trunk links, set **Allowed VLANs** to **All**. Specify a native VLAN.
- If you choose **dynamic auto** or **dynamic desirable** as the switch mode, enter the access VLAN ID. Enter the VLAN IDs you want to assign as trunk links. To allow all VLAN IDs as trunk links, set the **Allowed VLANs** to All. Specify a native VLAN.

g) Click **Update & Apply to Device**.

Create a port-channel interface (CLI)

Create a port-channel interface using commands.

Configure a port-channel interface to aggregate multiple network interfaces for increased bandwidth or redundancy.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the port channel and enter interface configuration mode.

   Example

   ```
   Device(config)# interface port-channel port-channel 2
   ```

   The valid values for the port channel number ranges from one to 64.

3. Configure the port as trunk.

   Example

   ```
   Device(config-if)# switchport mode trunk
   ```

4. Enable the interface.

   Example

   ```
   Device(config-if)# no shutdown
   ```

Configure LAG in ON mode (CLI)

Configure LAG in ON mode using commands.

Group multiple physical interfaces for increased bandwidth and redundancy using LAG in ON mode.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the port.

   Example

   ```
   Device(config)# interface TenGigabitEthernet port-slot 0/0/0
   ```

3. Configure the port as trunk.

   Example

   ```
   Device(config-if)# switchport mode trunk
   ```

4. Disable the interface.

   Example

   ```
   Device(config-if)# no shutdown
   ```

5. Assign the port to a channel group, and specify the ON mode.

   Example

   ```
   Device(config-if)# channel-group group-number 3 mode on
   ```

   The valid values for the port channel number ranges from 1 to 64.

6. Assign the allowed VLAN ID to the port when it is in trunking mode.

   Example

   ```
   Device(config-if)# switchport trunk allowed vlan vlan-id 16,17
   ```

Add an interface to a port channel (LACP) (CLI)

Add and configure the interface to a port channel (LACP) using commands.

Assign an Ethernet interface to a port channel using LACP mode to aggregate bandwidth and provide redundancy.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the port.

   Example

   ```
   Device(config)# interface TenGigabitEthernet port-slot 0/0/0
   ```

3. Assign the port to a channel group, and specify the LACP mode.

   Example

   ```
   Device(config-if)# channel-group group-number 1 mode {active | passive}
   ```

   The valid values for the port channel number ranges from 1 to 64.

4. Configure the port as trunk.

   Example

   ```
   Device(config-if)# switchport mode trunk
   ```

Add an interface to a port channel (PAgP) (CLI)

Add and configure the interface to a port channel (PAgP) using commands.

Add and configure an interface as a member of a port channel using PAgP.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the TenGigabit Ethernet interface.

   Example

   ```
   Device(config)# interface TenGigabitEthernet port-slot 0/0/0
   ```

3. Assign the port to a channel group, and specify the PAgP mode.

   Example

   ```
   Device(config-if)# channel-group group-number 1 mode {auto | desirable}
   ```

   The valid values for the port channel number ranges from one to 64.

4. Configure the port as trunk.

Example

```
Device(config-if)# switchport mode trunk
```

Add a VLAN to a port channel (CLI)

Add different VLANs under a port channel using commands.

Add one or more VLANs to the list of allowed VLANs on a port channel.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the port channel.

Example

```
Device(config)# interface port-channel port-channel 1
```

The valid values for the port channel number range from one to 64.

3. Add VLANs to the list of allowed VLANs.

Example

```
Device(config-if)# switchport trunk allowed vlan vlan-id 10,30,50
```

Remove a port channel group from a physical interface (CLI)

Remove a port channel group from a physical port using commands.

Remove a port channel group binding from a specified physical interface to release it from port channel configuration.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the TenGigabit Ethernet interface.

Example

```
Device(config)# interface TenGigabitEthernet port-slot 0/0/0
```

3. Remove the port channel group from the physical port.

Example

```
Device(config-if)# no channel-group
```

4. Exit the interface configuration mode.

Example

```
Device(config-if)# end
```

Verify the LAG configuration

Verify a port channel's state using commands.

To view a port channel's state, use the following command:

```
Device# show etherchannel summary

                                Flags:  D - down        P - bundled in
port-channel
                                I - stand-alone s - suspended
                                H - Hot-standby (LACP only)
                                R - Layer3      S - Layer2
                                U - in use      f - failed to allocate
aggregator

                                M - not in use, minimum links not met
                                u - unsuitable for bundling
                                w - waiting to be aggregated
                                d - default port
                                A - formed by Auto LAG
                                Number of channel-groups in use: 1
                                Number of aggregators:           1
                                Group  Port-channel  Protocol    Ports

------+-------------+-----------+-----------------------------------------------

                                3      Po3(SU)         LACP
Tw0/0/0(P)      Tw0/0/1(P)
                                4      Po4(SU)         LACP
Tw0/0/2(P)      Tw0/0/3(P)
```

To verify an LACP or PAgP configuration, use the following commands:

```
Device# show running-config interface tenGigabitEthernet 0/0/0

                                Building configuration...
```

```
                                Current configuration : 114 bytes
                                !
                                interface TwoGigabitEthernet0/0/0
                                switchport trunk allowed vlan 16,17
                                switchport mode trunk
                                speed 1000
                                no negotiation auto
                                no snmp trap link-status
                                channel-group 3 mode on
```

```
Device# show running-config interface port-channel 1

                                Building configuration...

                                Current configuration : 54 bytes
                                !
                                interface Port-channel1
                                switchport mode trunk
                                switchport trunk allowed vlan 10,30,50
                                end
```

11 Reload Reason History

Topics:

- Reload reason history

Introduces the reload reason history feature for tracking device restart events and guides users through retrieving and verifying reload information using YANG data models.

Reload reason history

Describes a diagnostic and serviceability feature that records controller reload events and maintains historical data for troubleshooting purposes.

Reload reason history is a diagnostic and serviceability feature that

- records the reasons for controller reloads
- maintains a log of the last ten reload events, and
- provides access to this data through CLI commands or programmable interfaces like NETCONF/YANG.

This feature is useful for troubleshooting abnormal reboots and understanding system behavior in production environments. Cisco introduced it in IOS XE Dublin 17.11.1, enhancing previous capabilities that only recorded the last reload reason.

View reload reason history

View the history using the **show version** command and the Network Configuration Protocol (NETCONF).

> **Note**
>
> When you reload the standby controller, the system report files are generated in the controller hard disk.

Feature history

Lists feature history for reload reason history.

This reference provides the feature history for reload reason history functionality.

Table 14: Feature history for reload reason history

Feature name	Release information	Feature description
Reload reason history	Cisco IOS XE 17.11.1	The reload reason history feature tracks the reasons for controller reload. This is done for the last 10 reloads. In Cisco IOS-XE 17.10.x and earlier releases, it was possible to track only the reason for the last reload.

Request reload reason history using YANG

Configure YANG with NETCONF and RESTCONF to request reload reason history for automated and programmable network operations.

Use YANG with NETCONF and RESTCONF to provide the desired solution for automated and programmable network operations.

Procedure

Use RPC to create a NETCONF GET request for reload history data.

Example

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e">
  <nc:get>
    <nc:filter>
      <device-hardware-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-device-hardware-oper">
        <device-hardware>
          <device-system-data>
            <reload-history/>
          </device-system-data>
        </device-hardware>
      </device-hardware-data>
    </nc:filter>
  </nc:get>
</nc:rpc>

<rpc-reply message-id="urn:uuid:da15955f-5bb7-437c-aeb5-0fc7901a1e9e"
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <device-hardware-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-device-hardware-oper">

Part II

System Upgrade

Topics:

- Upgrade the Cisco Catalyst 9800 Wireless Controller Software
- In-Service Software Upgrade
- Staggered AP Upgrade
- Software Maintenance Upgrade
- Efficient Image Upgrade and Out-of-band AP Image Download
- Predownloading an Image to an Access Point
- N+1 Hitless Rolling AP Upgrade
- NBAR Dynamic Protocol Pack Upgrade
- Wireless Sub-Package for Switch

12 Upgrade the Cisco Catalyst 9800 Wireless Controller Software

Topics:

- Software upgrade for Cisco Catalyst 9800 Series Wireless Controller

Details upgrade procedures for the Cisco Catalyst 9800 Wireless Controller, outlining key concepts, step-by-step instructions for both GUI and CLI methods, conversion between bundle and install modes, and the process for copying a WebAuth tar bundle to a standby controller.

Software upgrade for Cisco Catalyst 9800 Series Wireless Controller

Methods to upgrade the Cisco Catalyst 9800 Series Wireless Controller Software.

A software upgrade for Cisco Catalyst 9800 Series Wireless Controllers is a series of improvements and maintenance updates that:

- introduce new features and enhancements with each major release,
- offer various upgrade methods including full image upgrades and bug patch applications, and
- support upgrading through either GUI or CLI interfaces for user convenience.

This section describes the upgrade process and the methods to upgrade the Cisco Catalyst 9800 Series Wireless Controller Software.

Newer versions of the controller software are released at regular intervals. This includes major releases as well as rebuild releases that focuses on bug fixes. The version of the AP software is also tied to the controller software release. Every major Cisco IOS XE software release contains new sets of features that are essential for the enterprise-class customers.

Based on your requirement, such as upgrading the full image or applying a software patch for bugs, you can go for an appropriate software upgrade, using either GUI or CLI.

- Upgrade the Controller Software (GUI)
- Upgrade the Controller Software (CLI)

Software Upgrade Options

- **Software Maintenance Upgrade**: This method installs a software package on the system to provide a patch fix or a security resolution to a released image. This upgrade package is provided on a per release and per component basis, and is specific to the platform.
- **Hitless Upgrade**: This method allows the APs to be upgraded in a staggered manner, while still being connected to the same controller. This avoids upgrade downtime even for N+1 networks.
- **In-Service Software Upgrade**: This method upgrades a wireless controller image to a later release while the network forwards packets. This feature is supported only within and between major releases.

> **Note**
>
> We recommend In-Service Software Upgrade if you are upgrading the entire image or cold controller SMU. Use Software Maintenance Upgrade for software patches or bug fixes.

The software upgrade time is estimated to be less than 6 hours for a large network. However, the upgrade time depends on factors such as the number of APs, the percentage of APs to upgrade in each iteration, the controller type (9800-80, 9800-L, and so on), and the connectivity between the controller and the APs.

Device Upgrade Options

The following device upgrade options are available:

- NBAR Dynamic Protocol Pack Upgrade: Protocol packs are software packages that update the Network-Based Application Recognition (NBAR) engine protocol support on a device without replacing the Cisco software on the device. A protocol pack contains information on applications that are officially supported by NBAR, and are compiled and packed together.

- Field Programmable Upgrade: These are hardware programmable packages released by Cisco to upgrade the hardware programmable firmware. Hardware programmable package upgrade is necessary only when a system message indicates that one of the field programmable devices needs an upgrade or when a Cisco technical support representative suggests an upgrade.

Upgrade the controller software using GUI

Upgrade the controller software using GUI.

The purpose of this task is to guide users through the process of upgrading the controller software via the graphical user interface (GUI), ensuring a seamless transition to the latest version.

- Ensure device configurations remain intact during the upgrade process.
- Provide an option for users to select their preferred upgrade and transport modes.

Before you begin

Clean up the old installation files using the **Remove Inactive Files** link.

- Software Maintenance Upgrade
- AP Service Package
- AP Device Package

Procedure

1. Choose **Administration > Software Management** .
2. Choose an option from the **Upgrade Mode** drop-down list:
   - **INSTALL**: The Install mode uses a package-provisioning file named *packages.conf* in order to boot a device.
   - **BUNDLE**: The Bundle mode uses monolithic Cisco IOS images to boot a device. The Bundle mode consumes more memory than the Install mode because the packages are extracted from the bundle and copied to RAM.

   Note

   You get to view the **Destination** field only for BUNDLE upgrade mode.

3. From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as **TFTP**, **SFTP**, **FTP**, **Device**, or **Desktop (HTTP)**.

   Table 15: Transport Type Options

If...	Then...
You choose **TFTP** as the **Transport Type**	Enter the **Server IP Address** of the TFTP server that you want to use. Also, enter the complete **File Path**. In controllers, the IP TFTP source is mapped to the service port by default.

If...	Then...
You choose **SFTP** as the **Transport Type**	Enter the **Server IP Address** of the SFTP server that you want to use. Also, enter the **SFTP Username**, **SFTP Password**, and the complete **File Path**.
You choose **FTP** as the **Transport Type**	Enter the **Server IP Address** of the FTP server that you want to use. Also, enter the **FTP Username**, **FTP Password**, and the complete **File Path**.
You choose **Device** as the **Transport Type**	Choose the **File System** from the drop-down list. In the **File Path** field, browse through the available images or packages from the device and select one of the options, and click **Select**.
You choose **Desktop (HTTPS)** as the **Transport Type**	Choose the **File System** from the drop-down list. In the **Source File Path** field, click **Select File** to select the file, and click **Open**.

4. Click **Download & Install**.
5. To boot your device with the new software image, click **Save Configuration & Activate**.
6. Click **Commit** after the device reboots to make the activation changes persistent across reloads.

> **Note**
>
> For 17.4 and later releases, this step is mandatory for the upgrade to be persistent. If you do not click **Commit**, the auto-timer terminates the upgrade operation after 6 hours, and the controller reverts back to the previous image.

After completing the upgrade, the controller runs the latest version of the software, maintaining continuity and performance enhancements brought by the new update.

Upgrade the controller software (CLI)

Upgrade the controller software using CLI.

The purpose of this task is to update the controller software to the latest version using CLI to ensure optimal performance and security.

Before you begin

- Determine the Cisco IOS release that is currently running on your controller, and the filename of the system image using the **show version** command in user EXEC or privileged EXEC mode.
- Clean up the old installation files using the **install remove inactive** command.
- Use the **show version | include Installation mode** to verify the boot mode.

> **Note**
>
> We recommend that you use install mode for the software upgrade.

For steps on converting the device from bundle-mode to install-mode, see Converting from Bundle-Mode to Install-Mode.

Procedure

1. Download the software from Cisco.com: https://software.cisco.com/download/home/286322524
   - Click IOS XE Software link.
   - Select the release number you want to install, for example Gibraltar-16.12.3.

     > **Note**
     >
     > Cisco recommended release is selected by default. For release designation information, see: https://software.cisco.com/download/static/assets/i18n/reldesignation.html?context=sds

   - Click **Download**.
2. Copy the new image to flash using the command: **copy tftp:***image* **flash:**
3. Verify that the image has been successfully copied to flash using the command: **dir flash:**
4. Upgrade the software by choosing an upgrade process from the options that are currently supported.

   For a list of upgrade options, see Software Upgrade Options on page 202.

Upon completing this task, the controller software will be successfully upgraded to the latest version, enhancing device functionality and security.

Convert from bundle-mode to install-mode

Convert From Bundle-Mode to Install-Mode.

Use the procedure given below to boot in install-mode:

Before you begin

- Clean up the old installation files using the command **install remove inactive**
- Verify the boot mode using the command: **show version | include Installation mode**
- Download the software image from Cisco.com.

  For steps on how to download the software, see *Upgrading the Controller Software (CLI)*

Procedure

1. Copy the new image to flash using the command: **copy tftp:*image* flash:**

```
Device# copy tftp://xx.x.x.x//C9800-universalk9_wlc.xx.xx.xx.SSA.bin flash:

Destination filename [C9800-universalk9_wlc..xx.xx.xx..SSA.bin]?
Accessing tftp://xx.x.x.x//C9800-universalk9_wlc.xx.xx.xx.SSA.bin...
Loading /C9800-universalk9_wlc.xx.xx.xx.SSA.bin from xx.x.x.x (via
GigabitEthernet0/0):
!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
[OK - 601216545 bytes]
601216545 bytes copied in 50.649 secs (11870255 bytes/sec)
```

2. Verify that the image has been successfully copied to flash using the command: **dir flash:**

```
Device# dir flash:*.bin

Directory of bootflash:/*.bin

On Active

Directory of bootflash:/

   12  -rw-  1231746613  Jun 11 2020 23:15:49 +00:00

   18  -rw-  1232167230   Jun 8 2020 02:42:22 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200607_002322.SSA.bin
24811823104 bytes total (16032391168 bytes free)

On Standby
Directory of stby-bootflash:/*.bin

Directory of stby-bootflash:/

   18  -rw-  1232167230   Jun 8 2020 02:42:22 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200607_002322.SSA.bin
   20  -rw-  1231746613  Jun 11 2020 23:15:49 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200611_101837.SSA.bin
   17  -rw-  1232457039   Jun 9 2020 21:14:40 +00:00
C9800-universalk9_wlc.BLD_POLARIS_DEV_LATEST_20200609_031801.SSA.bin
   16  -rw-  1219332990  Jun 10 2020 02:06:14 +00:00
C9800-universalk9_wlc.BLD_V173_THROTTLE_LATEST_20200608_003622_V17_3_0_183.SSA.bin
26462998528 bytes total (17686335488 bytes free)
```

3. Set the boot variable to **bootflash:packages.conf**.

```
Device(config)# boot sys flash bootflash:packages.conf
```

4. Save your changes by entering this command: **write memory**.

```
Device(config)# write memory
```

> **Note**
>
> For this configuration, the mode changes from enable to config mode.

5. Verify whether the boot variable is set to bootflash:packages.conf using the command: **show boot**

```
Device# show boot

BOOT variable = bootflash:packages.conf,12;
CONFIG_FILE variable =
BOOTLDR variable does not exist
Configuration register is 0x2102

Standby BOOT variable = bootflash:packages.conf,12;
Standby CONFIG_FILE variable =
Standby BOOTLDR variable does not exist
Standby Configuration register is 0x2102
```

6. Move the device from bundle-mode to install-mode using the command: **install add file** *image.bin location* **activate commit**

```
Device# install add file bootflash:C9800-universalk9_wlc.xx.xx.xx.SPA.bin
activate commit

install_add_activate_commit: START Thu Dec 6 15:43:57 UTC 2018

SUCCESS: install_add_activate_commit Thu Dec 6 15:49:21 UTC 2018
Dec 6 15:49:21.294 %INSTALL-5-INSTALL_COMPLETED_INFO: R0/0: install_engine:
Completed
install one-shot PACKAGE bootflash:C9800-xx-universalk9.xx.xx.xx.SPA.bin
```

Note

The system reloads automatically after executing the **install add file activate commit** command. You do not have to manually reload the system.

If upgrade fails, cleanup is required before attempting the upgrade procedure again. An upgrade failure may occur due lack of disk space, validation failure of extracted image, system crashes, and so on. Should a system failure occurs during upgrade process, wait till the system is back in service and check the system image version.

- If it is a new image, check for the stability and functionality of the system, and decide whether to commit and complete the upgrade procedure or discard the upgrade procedure.
- If it is a new image, use the cleanup procedure and reattempt the upgrade procedure.

7. Click **yes** to all the prompts.
8. Verify the boot mode using the command: **show version**

```
Device# show version | in Installation mode is

Installation mode is INSTALL
```

Copy a WebAuth tar bundle to the standby controller (GUI)

Copy a WebAuth tar bundle to the standby controller in a high-availability configuration.

Ensure the standby controller receives the WebAuth tar bundle to maintain seamless high-availability functionality.

Copy a WebAuth tar bundle to the standby controller in a high-availability configuration.

Procedure

1. Go to **Administration** , select **Management** , and then select **Backup and Restore**.
2. Select **To Device** from the **Copy** drop-down list.
3. Select **WebAuth Bundle** from the **File Type** drop-down list.
4. Select **TFTP** , **SFTP** , **FTP** , or **HTTP** from the **Transfer Mode** drop-down list.

   The required values for the **Server IP Address** and **File Path** fields depend on the selected transfer mode.

   - **TFTP**
     - **IP Address (IPv4/IPv6)** : Enter the server IP address (IPv4 or IPv6) of the TFTP server you want to use.
     - **File Path**: Enter the file path. Start the file path with a slash, such as */path*.
     - **File Name**: Enter a file name.

       Do not use spaces in the file name. Use underscores and hyphens. Make sure the file name ends with .tar, for example, webauthbundle.tar.
   - **SFTP**
     - **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the SFTP server that you want to use.
     - **File Path**: Enter the file path. Start the file path with a slash, such as */path*.
     - **File Name**: Enter a file name.

       Do not use spaces in the file name. Only underscores and hyphens are allowed. Make sure the file name ends with .tar, for example, webauthbundle.tar.
     - **Server Login Username**: Enter the SFTP server login user name.
     - **Server Login Password**: Enter the SFTP server login passphrase.
   - **FTP**
     - **IP Address (IPv4/IPv6)**: Enter the server IP address (IPv4 or IPv6) of the FTP server that you want to use.
     - **File Path**: Enter the file path. Start the file path with a slash, such as */path* .
     - **File Name**: Enter a file name.

       Do not use spaces in the file name. Only underscores and hyphens are allowed. Make sure the file name ends with .tar, for example, webauthbundle.tar.
     - **Logon Type**: Choose **Anonymous** or **Authenticated** . If you choose **Authenticated**, these fields are activated:
       - **Server Login Username**: Enter the FTP server login user name.
       - **Server Login Password**: Enter the FTP server login passphrase.
   - **HTTP**

- **Source File Path**: Click **Select File** to select the configuration file, and click **Open**.

5. Click the **Yes** or **No** radio button to back up the existing startup configuration to Flash.

   Save the configuration to Flash to propagate the WebAuth bundle to other members, including the standby controller.

6. Click **Download File**.

The WebAuth tar bundle is successfully copied to the standby controller, ensuring high-availability readiness.

13 In-Service Software Upgrade

Topics:

- In-service software upgrade (ISSU)

In-service software upgrade (ISSU)

Explains how In-Service Software Upgrades (ISSUs) allow network administrators to upgrade Cisco wireless controllers without disrupting network packet forwarding.

An In-Service Software upgrade (ISSU) is a wireless controller procedure that

- upgrades the controller software image to a later release while the network continues to forward packets
- enables administrators to avoid network outages during software upgrades, and
- allows cold patches to be applied without impacting the active network.

ISSU is supported only on these Cisco Catalyst 9800 Series Wireless Controllers. It supports only upgrade operations.

- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800-L Wireless Controller
- Cisco Catalyst 9800-CL Wireless Controller (Private Cloud)
- Cisco Wireless 9800M Wireless Controller
- Cisco Wireless 9800H1/H2 Wireless Controller

High-Level Workflow of ISSU

1. Onboard the controller software image to the flash memory.
2. Download the AP image to the AP.
3. Install the controller software image.
4. Commit the changes.

Table 16: Feature history for In-Service Software Upgrade (ISSU)

Feature Name	Release Information	Feature Description
In-Service Software Upgrade (ISSU)	Cisco IOS XE 17.1.1s	This feature upgrades an image to another image on a device while the network continues to forward packets. ISSU helps network administrators avoid a network outage when performing a software upgrade.

Prerequisites for performing ISSU

Prerequisites for Performing ISSU.

- Ensure that both Active and Standby controllers are in install mode and are booted from *bootflash:/packages.conf*.
- Ensure that the network or device is not being configured during the upgrade.
- Schedule the upgrade when your network is stable and steady.
- Ensure that the system has an uninterrupted power supply. A power interruption during the upgrade procedure can corrupt the software image.

Guidelines for ISSU

ISSU guidelines and restrictions.

- During ISSU upgrade, the system displays a warning message similar to:

  ```
  found 46 disjoint TDL objects
  ```

  The warning message does not impact system functionality.

- During ISSU upgrade, if both the controllers (active and standby) have different images after the power cycle, an auto cancel of ISSU is triggered to bring both the controllers to the same version. The following is a sample scenario: Install Version 1 (V1) software on the active controller. Apply a SMU hot patch. Perform a commit. Upgrade to Version 2 using ISSU. Power cycle the active controller. The system now has a version mismatch (V1 and V2). After bulk synchronization, the active controller reloads. Both controllers have the same version (V1 and V1).
- To enable the **clear install** command, you should first run the **service internal** command in global configuration mode, and then run the **clear install** command in privileged EXEC mode.
- A stale rollback history can affect image rollback after the stack forms. We recommend running the **clear install state** command to clear stale information and boot the controller in bundle mode.
- After the image upgrade, when the new active controller starts up, it does not retain the old logs on the web GUI window as part of show logs.
- During a stateful switchover (SSO) or HA event, the rolling AP upgrade stops. Use the **ap image upgrade** command to restart the upgrade process.
- Use the clear **ap predownload statistics** running the **show ap image** command. This ensures you get accurate data after every pre-download.
- To avoid a software version mismatch between the active and standby controller, manually cancel the ISSU process by using the **install issu abort** command in the appropriate scenarios.
  - The system may disable an RP link after standby HOT during an ISSU procedure. The link stays down after the auto-abort timer expires.
  - An RP link is brought down before the standby controller reaches standby HOT during an ISSU procedure.
- The ISSU upgrade from version 17.12 to 17.15 fails if WPA3 suite-b-192, suite-b, gcmp128, gcmp256, or ccmp256 are already configured.

Restrictions for ISSU

- If you do not run the **install commit** command within six hours of the **install activate issu** command, the system reverts to the original commit position. Delay the commit by using the Delayed Commit procedure.
- You cannot use the **install abort** command during the AP rolling upgrade. You should use the **install abort issu** command, instead to cancel the upgrade.
- If configuration synchronization fails on the standby controller, the ISSU upgrade cancels and rolls back to software image V1. However, this information isn't available in the **show install** command log. Run the **show issu state detail** command to see the current ISSU state.
- The **clear install state** command doesn't delete the SMU file from flash or storage. To remove a SMU, use either the **install remove file** command or the **install remove inactive** command.
- If HA does not form after the ISSU procedure, reload one chassis.
- You cannot use Cisco TrustSec (CTS) on RMI interfaces.

- If a switchover occurs while performing an AP upgrade using ISSU, the upgrade process will restart automatically after the switchover.

Upgrade software using ISSU (CLI)

Upgrade software using ISSU using commands.

Use this procedure to upgrade the image from one version to another.

Note

ISSU is supported only within and between major releases. For example, upgrades are supported from 17.3.*x* to 17.3.*y* or 17.6.*x* to 17.6.*y* (within a major release), as well as from 17.3.*x* to 17.6.*x* and from 17.3.*x* to 17.9.*x* (among major releases). For more information, check https://www.cisco.com/c/en/us/td/docs/wireless/controller/9800/tech-notes/b_issu_9800.html#id_129557. ISSU is not supported within or between minor releases or between minor and major releases. For example, upgrades such as 17.4.*x* to 17.4.*y*, 17.4.*x* to 17.5.*x* or 17.3.*x* to 17.4.*x* are not supported.

ISSU downgrade is not supported for Cisco Catalyst 9800 Series Wireless Controller platforms.

Note

We recommend configuring the percentage of APs to be upgraded by using the ***ap upgrade staggered*** command.

Procedure

1. Install the file to expand the wireless package file.

   Example

   ```
   Device# install add file file-name
   ```

   The controller software image is added to the flash and expanded.

   Note

   In Cisco Catalyst 9800 Wireless Controller for Switch, run the **install add file** *sub-package-file-name* command to expand the wireless subpackage file.

2. Perform predownload of the AP image.

   Example

   ```
   Device# ap image predownload
   ```

   To see the progress of the predownload, use the **show ap image** command.

3. Run compatibility checks, install the package, and update the package status details.

   Example

   ```
   Device# install activate issu [auto-abort-time timer]
   ```

   Optionally, you can configure the time limit to cancel the addition of new software without committing the image. The valid values are from 30 to 1200 minutes.

4. Run either of the following commands:

   - Cancel the upgrade process and return to the device to the previous installation state.

     ```
     Device# install abort issu
     ```

     This is applicable for both controller and the AP.

   - Commit the activation changes to be persistent across reloads.

     ```
     Device# install commit
     ```

     Note

     If you do not run the **install commit** command within 6 hours of completing the previous step, the system will revert to the original commit position.

Upgrade software using ISSU (GUI)

Upgrade software using ISSU using GUI.

Before you begin

1. The device should be in Install mode.
2. It should also have a high-availability (HA) pair. The standby controller should be online and in SSO mode.

   You can verify the details using **show issu state detail** command.

Procedure

1. Choose **Administration** > **Software Management**.
2. Check the **ISSU Upgrade (HA Upgrade) (Beta)** check box under the **Software Upgrade** tab.
3. Select the **AP Upgrade per Iteration** percentage option of APs to be upgraded from the drop-down list in the **AP Upgrade Configuration** section.
4. Click **Download & Install**.

   This initiates the upgrade process and you can view the progress in the **Status** dialog box.

   Click the **Show Logs** link to view the upgrade process details.

> **Note**
>
> An SSO takes place while activating the image on the active controller. After the SSO, you should login again to the controller.

5. The system enables the **Commit** and **ISSU Abort** buttons after the upgrade.

   Click **Commit** to commit the activation changes, or **ISSU Abort** to terminate the upgrade process and return the device to the previous installation state.

Upgrade software using ISSU with delayed commit (CLI)

Upgrade the controller software using ISSU with delayed commit.

Use this procedure to upgrade the controller software with delayed commit. This lets you run and test the new software without committing the image.

Procedure

1. Add and expand the controller software image to the flash.

   Example

   ```
   Device# install add file file-name
   ```

   > **Note**
   >
   > In Cisco Catalyst 9800 Wireless Controller for Switch, run the **install add file** *sub-package-file-name* command to expand the wireless subpackage file.

2. Perform predownload of the AP image.

   Example

   ```
   Device# ap image predownload
   ```

3. Run compatibility checks, install the package, and update the package status details.

   Example

   ```
   Device# install activate issu
   ```

   The ISSU completes activation and a message that the **terminal state is reached** is displayed in the **show issue state detail** command output.

4. Stop the termination timer.

Example

```
Device# install auto-abort-timer stop
```

This ensures that the upgrade process is not terminated after the default termination time of six to eight hours.

5. Commit the activation changes to be persistent across reloads.

Example

```
Device# install commit
```

6. Optional: Abort ISSU and go back to the previous version.

Example

```
Device# install abort issu
```

Monitor ISSU

Monitor ISSU using these commands.

To view the ISSU state after the install add ISSU and before the install activate ISSU, use the command:

```
Device# show issu state detail

-- Starting local lock acquisition on chassis 1 ---
Finished local lock acquisition on chassis 1
Current ISSU Status: Enabled
Previous ISSU Operation: Abort Successful
=====================================================

14 Staggered AP Upgrade

Topics:

- Access point upgrade configurations

Access point upgrade configurations

Learn about access point upgrade configurations and how to customize upgrade processes in your network..

Access point upgrade configuration are controller software parameters that:

- control the number of APs upgraded in each batch or iteration,
- include several upgrade strategies (including new staggered and serial modes), and
- are applicable across all upgrade scenarios such as In-Service Software Upgrade (ISSU), N+1 Hitless Rolling AP Upgrade, and Access Point Service Pack (APSP) or Access Point Device Package (APDP).

These configurations stagger AP updates, and provide more flexibility in large network environments.

> ⚠ **Caution**
>
> Avoid using these configurations for wncd-config upgrades (such as Locally Significant Certificate [LSC] renewal).

Examples of upgrade

- One percent per iteration: Only one percent of APs are upgraded at a time, minimizing disruption.
- Serial: One AP is upgraded at a time, resulting in the least disruption but taking much longer.

Feature history for access point upgrade management enhancements

AP Power Save feature history.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 17: Feature history for access point upgrade management enhancements

Release	Feature Information
Cisco IOS XE 17.18.1	Provides configurations for reduced AP batch size used during AP upgrades. These configurations aim to reduce disruption during the upgrade process by providing even greater control over AP upgrade batch sizes. Since the batch sizes can be greatly reduced, such configurations should not be used during maintenance windows as it would result in long upgrade time The following commands are modified: • **ap upgrade staggered** . Two new keywords **1** and **serial** are introduced. • **show ap upgrade** The YANG model changes include new options for AP upgrade configurations and marking the node **stgrd-upgd-ap** as obsolete to support 6000 APs. The new node **comp-ap** lists APs with successfully completed upgrade.

Access point upgrade configuration and behavior

AP Upgrade batch sizes.

New configurations and operational changes in controller software give you more control over access point (AP) upgrade processes.

Here are the enhancements:

- You have more granular control with AP upgrade batch sizes, allowing minimum disruption of your network.
- You can use serial and one percent per-iteration upgrade modes to perform in-service upgrades.

> **Note**
>
> These new configurations must be used strictly outside the maintenance windows. See Warning: Extended upgrade durations for serial and one percent batch modes on page 224.

- The CLI and YANG models now support these options, so that you can manage upgrades more effectively.

These changes help you reduce service impact during AP upgrades and are particularly useful for large-scale or in-service environments.

Staggered and serial AP upgrade concepts

Learn about staggered and serial access point upgrade concepts for minimizing client impact during upgrades.

A staggered and serial AP upgrade concept is a network upgrade methodology that:

- sequentially updates subsets of access points (APs) to minimize client impact,

- allows configuration of different batch sizes, including single AP upgrades, and
- provides options for client steering and de-authentication controls to optimize network continuity during in-service upgrades.

When the AP batch size is small, the rollout process may be slower. However, because very few APs are affected in each iteration, clients have many options to retain connectivity, and large networks benefit from improved network performance.

Staggered upgrades distribute the process across multiple iterations. Serial upgrades process one AP per iteration. Use these approaches when service continuity is critical during in-service upgrades

Controller CLI enhancements for AP upgrade management

Learn about new CLI commands that help you manage AP upgrades.

Controller CLI enhancements for AP upgrade management are:

- New keywords **serial** and **1** added to the **ap upgrade staggered** command specifying serial mode and upgrade batch sizes.
- Warnings are issued for configurations that may lead to extended upgrade durations.
- The output of **show ap upgrade** now reflects the new upgrade processes.

These changes help you configure and monitor upgrades more precisely and with greater awareness of possible service impacts.

For more information about these commands, see **ap upgrade staggered** and **show ap upgrade**

Warning: Extended upgrade durations for serial and one percent batch modes

If you choose serial or one percent per iteration upgrades, the process can take a long time. For example, 6000 APs at three minutes takes over 12 days). Use these modes only when minimizing disruption is more important than upgrade speed.

Configure staggered or serial AP upgrades

Configure the wireless controller to upgrade access points in staggered batches or one at a time, minimizing client disruption.

Use this task to perform upgrades in large, production, or in-service environments where minimizing service impact is crucial.

Follow these steps to configure staggered or serial AP upgrades:

You can also configure these options through the GUI. See Configure AP certificate auto-renewal (LSC) (GUI) on page 1760

Before you begin

- Review network size and upgrade impact to select an appropriate mode.

Procedure

1. Enter global configuration mode.
2. Use the **ap upgrade staggered** command to view available options and select a batch size:
   - Enter 1 for one percent per iteration (minimal disruption, slowest).
   - Enter serial for one AP at a time (least disruption, longest duration).

- Enter 5, 15, or 25 for other batch percentages as needed.

3. Optional: Configure client de-authentication or steering.
   The controller displays a warning if **serial** or **1%** mode is selected.
4. Exit the global configuration mode.

After you complete these steps, the controller staggers AP upgrades based on your configuration.

CLI and GUI options for upgrading APs

The AP upgrade management options available on CLI and GUI

The table lists CLI and GUI options for upgrading APs.

Table 18: CLI and GUI options for upgrading APs

Command Option	Description
1	1% of APs per iteration
5	5% of APs per iteration
15	15% of APs per iteration
25	25% of APs per iteration
client-deauth	Enable or disable client de-authentication
client-steering	Enable or disable client steering
iteration	Configure iteration accounting parameters
one-shot	Upgrade all APs in a single iteration
serial	Upgrade one AP at a time

YANG Model Update

The YANG oper model for **ap-upgrade status** with **stgrd-upgd-ap** is obsolete starting with Cisco IOS XE Release 17.18.x.

A new xpath with **comp-ap** is introduced to support newer APs. The list includes all the APs that have completed the upgrade operation.

Old XPATH

```
xpath /access-point-oper-data/stgrd-upg-report/stgrd-upgd-ap
```

NEW XPATH

```
xpath /access-point-oper-data/stgrd-upg-report/comp-ap
```

Node properties of comp-ap

```
Name            comp-ap
nodetype        list
description     List of APs with successfully completed upgrades. This is the
 new list for upgraded APs, with support for serial AP upgrades.
module          Cisco-IOS-XE-wireless-access-point-oper
revision        2025-07-01
```

```
xpath           /access-point-oper-data/stgrd-upg-report/comp-ap
prefix          wireless-access-point-oper
namespace      http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-access-point-oper
schema node id  /access-point-oper-data/stgrd-upg-report/comp-ap
Keys            "iter-number""radio-mac"
access          read-only
operations      "get"
```

15 Software Maintenance Upgrade

Topics:

- Software maintenance upgrade
- AP device package
- Per site or per AP model service pack (APSP)

Software maintenance upgrade

Explains how software maintenance upgrades (SMUs) provide targeted, platform-specific patches and security fixes for released images on Cisco IOS XE systems.

A software maintenance upgrade (SMU) is a software package that

- is installed on a system to provide a patch or a security fix resolution to a released image, and
- is on a per component basis and is specific to the corresponding platform.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 19: Feature history for Software maintenance upgrade

Feature Name	Release Information	Feature Description
Software maintenance upgrade	Cisco IOS XE Gibraltar 16.11.1b	This feature provides network administrators with targeted, platform-specific patches and security fixes for released images, applicable either on a per-component basis or for the entire corresponding platform.

A SMU offers significant benefits over classic Cisco IOS software. It lets you address network issues promptly and reduces required testing time and scope. The Cisco IOS XE platform validates SMU compatibility internally and prevents installation of non-compatible SMUs.

All SMUs are also integrated into subsequent Cisco IOS XE software maintenance releases. A SMU is an independent and self-sufficient package without prerequisites or dependencies. You can choose which SMUs to install or uninstall in any order.

Note

SMUs are supported only on Extended Maintenance releases and throughout the full lifecycle of the underlying software release.

Note

Activate the file using the **install add file** command only from the filesystems of the active device. If you use a file from the standby or member filesystems, the **install add file** command fails.

Note

When the SMU file is deleted and the device is rebooted, the device may display an error message such as:

```
--- Starting SMU Add operation ---
Performing SMU_ADD on all members
    FAILED: Improper
State./bootflash/<previously-installed-smu-filename>.smu.bin not present.
Please restore file for stability.
Checking status of SMU_ADD on [1/R0]
SMU_ADD: Passed on []. Failed on [1/R0]
Finished SMU Add operation
FAILED: add_activate_commit /bootflash/<tobeinstalled-wlc-smu-filename>.smu.bin
 Wed Aug 02 08:30:18 UTC 2023.
```

This error occurs because the previous SMU file was not properly removed from the controller. As a result, you may not be able to install new SMU or APSP files.

Use the **install remove file** command to remove previous instances of APSP or SMU files from the bootflash.

You can use SMU infrastructure to meet these requirements in wireless contexts:

- Controller SMU: Controller bug fixes or Cisco Product Security Incident Response information (PSIRT).
- APSP: APSP is used for AP bug fixes, PSIRTs, or minor features that do not require controller changes.
- APDP: APDP supports new AP models without introducing new hardware or software capabilities.

> **Note**
>
> The **show ap image** command displays cumulative statistics for AP images in the controller. Clear the statistics using the **clear ap predownload statistics** command, before using the **show ap image** command, to ensure correct data is displayed.

SMU Workflow

Begin the SMU process by requesting approval from the SMU committee. Contact customer support to raise an SMU request. During the release, the SMU package is posted on the Cisco Software Download page. You can then download and install it.

Warning: Commit changes within six hours of activation or deactivation to avoid rollback

Always run the **install commit** command within 6 hours after executing either **install activate** or **install deactivate** .

If you do not commit changes within this window

- the system automatically reverts to the previous commit state
- this reversion can lead to service interruption, especially over low-bandwidth links where image transfers may not complete in time, and
- remote deployments with slow transfer rates are particularly vulnerable.

To reduce these risks

- run **install commit** after activation or deactivation
- monitor image transfer progress proactively, and
- plan for available bandwidth and duration at remote sites.

SMU Package

An SMU package contains the metadata and the fix for the reported issue that prompted the request.

SMU Reload

The SMU type describes the effect on a system after you install a SMU. SMUs can be non-traffic-affecting, or they can require a device restart, reload, or switchover.

A controller cold patch requires a cold reload of the system during activation. A cold reload means completely restarting the operating system.

This process affects traffic during two phases:

- the reload of the wireless controller, and
- the time needed for all APs to rejoin the controller, receive the new image, and upgrade to the new SMU patch. This reload ensures that all processes use the correct libraries and files installed as part of the SMU.

The reload ensures all processes use the correct libraries and files installed as part of the SMU.

With controller hot patching, a SMU is effective immediately after activation, without rebooting the system. After you commit the SMU, activation changes persist across reloads. Hot patching SMU packages contain metadata listing processes to restart for activation. During activation, each process is restarted one by one until activation completes.

Install a SMU (GUI)

Install a SMU using GUI.

Add and activate a SMU image on your device using the GUI.

Procedure

1. Choose **Administration** > **Software Management** and click the **Software Maintenance Upgrade** tab.
2. Click **Add** to add a SMU image.
3. From the **Transport Type** drop-down list, select the transfer type, TFTP, SFTP, FTP, Device, or Desktop (HTTP) to transfer the software image to your device.
   a) If you choose **TFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **File path** and select a **File System** from the drop-down list. For example, if the SMU file is at the root of the TFTP server you can enter `/C9800-universalk9_wlc.17.03.02a.CSCvw55275.SPA.smu.bin` in the **File path** field.
   b) If you choose **SFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path** and select a **File System** from the drop-down list.
   c) If you choose **FTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and select a **File System** from the drop-down list.
   d) If you choose **Device** as the **Transport Type**, enter the **File path** and select a **File System** from the drop-down list. This is possible when the software is already present on the device due to an earlier download and activation, followed by a subsequent deactivation.

      Note

      Depending on your device, available file systems may vary. On physical controllers, store files on bootflash or hard disk. On virtual controllers, use bootflash.

   e) If you choose **Desktop (HTTPS)** as the **Transport Type**, select a **File System** from the drop-down list and click **Select File** to navigate to the **Source File Path**.
4. Enter the **File Name** and click **Add File**.

   When you complete this step, the maintenance update package is copied to the device, platform and image versions are checked for compatibility, and the SMU package is added for all members. After adding a SMU, you see a message indicating success and letting you know the SMU can be activated. The message displays the name of the package (SMU) that is available for activation. It lists the SMU details: Name, Version, State (active or inactive), Type (reload, restart, or non-reload), and other compatibility details. If the SMU type is 'reload,' any operation (activate, deactivate, or rollback) causes the device to reload. The 'restart' type involves only a process restart. If it is 'non-reload,' no process changes occur.
5. Select the SMU and click **Activate** to activate it on the system, install the package, and update the package status details.
6. Select the SMU and click **Commit** to make these activation changes persistent across reloads.

   The Commit operation creates commit points, which are similar to snapshots. Use commit points to decide which changes to activate or roll back if you have a problem with the SMU. You can commit after activation when the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload, but not after the second reload.

Install SMU (CLI)

Install SMU using commands.

Update device software with a SMU using CLI.

Procedure

1. Copy the maintenance update package from a remote location to the device, and perform a compatibility check for the platform and image versions.

   Example

   ```
   Device# install add file bootflash filename
   ```

   This command runs base compatibility checks on a file to verify that the SMU package is supported on the platform. The command also adds an entry to the package or SMU.sta file. This entry allows you to monitor and maintain the package's status.

2. Run compatibility checks, install the package and update the package status details.

   Example

   ```
   Device# install activate file bootflash filename
   ```

   For a restartable package, the command triggers the appropriate post-install scripts to restart the necessary processes. For non-restartable packages it triggers a reload.

3. Commit the activation changes to be persistent across reloads.

   Example

   ```
   Device# install commit
   ```

   You can perform the commit after activation while the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload; however, it is no longer active after the second reload.

4. Display the image version on the device.

   Example

   ```
   Device# show version
   ```

5. Display information about the active package.

   Example

   ```
   Device# show install summary
   ```

   The output of this command varies according to the install commands that are configured.

Roll back an image (GUI)

Roll back an image using GUI.

Return the software image on the system to a previous stable state using the GUI.

Procedure

1. Choose **Administration** > **Software Management**.
2. Go to **SMU**, **APSP** or **APDP**.
3. Click **Rollback**.
4. In the **Rollback to** drop-down list, select **Base**, **Committed** or **Rollback Point**.
5. Click **Add File**.

Roll back SMU (CLI)

Roll back SMU using commands.

Return the device to a previous software state by rolling back a SMU using CLI.

Procedure

1. Return the device to the previous installation state.

   Example

   ```
   Device(config)# install rollback to {base | committed | id | committed}
   committed ID id 1234
   ```

   After the rollback, a reload is required.

2. Commit the activation changes to be persistent across reloads.

   Example

   ```
   Device# install commit
   ```

Deactivate SMU (CLI)

Deactivate SMU using commands.

Deactivate an active SMU package on a network device using CLI.

Procedure

1. Deactivate an active package, update the package status, and trigger a process to restart or reload.

   Example

   ```
   Device# install deactivate file bootflash filename
   ```

2. Commit the activation changes to be persistent across reloads.

Example

```
Device# install commit
```

Configuration examples for SMU

Sample of the SMU configuration.

This example shows the SMU configuration after the system completes the install add for the SMU.

```
Device# show install summary

AP device package

Explains how AP device packages use the SMU infrastructure to extend wireless network support for new AP hardware without controller upgrades.

An AP device package is a software module that

- allows new AP hardware models to connect to an existing wireless network
- uses the SMU infrastructure to deliver new AP images, and
- enables flexible, out-of-cycle support for new AP devices independent of controller major releases.

AP Service Pack (APSP)

When a new AP hardware model is introduced, it is shipped along with the corresponding controller related major software version. Subsequently, you must wait for the release of a controller version compatible with the new AP model before upgrading the entire network.

Starting with version 16.11.1, you can add new AP models to your wireless network using the SMU infrastructure, without upgrading the controller version. This solution is called AP Device Package (APDP).

SMU Process or Workflow

The SMU process builds APDP to detect code changes and to build APDP. You can add new AP image files to APDP and include AP images as needed.

The workflow is as follows:

- install add
- install activate
- install commit

For more details, see Managing AP Device Package.

Warning: Commit changes within six hours of activation or deactivation

To complete the APSP or APDP activation or deactivation process, always run the **install commit** command within six hours after executing either **install activate** or **install deactivate**.

If you do not commit the changes within this window, the system reverts to the previous commit state automatically. Potential issues include:

- service interruptions, especially over low bandwidth links where image transfers may not finish in time, and
- rollbacks for remote deployments with slow transfer rates.

To avoid these risks:

- Run the **install commit** command immediately after activation or deactivation.
- Monitor the progress of the image transfer.
- Plan to have sufficient time available at remote sites.

SMU package and AP image changes

SMU Package

A SMU package is a software metadata unit that:

- contains AP model and capability-related details
- is updated when new AP models are introduced, and
- is bundled into APDP packages for deployment.

AP Image Changes

When new AP models are introduced, there may or may not be corresponding new AP images. AP images are mapped to the AP model families. If a new AP model belongs to an existing AP model family there will be existing AP image entries (for example: ap3g3 and ap1g5). If an AP model belongs to either ap3g3 or ap1g5, update the respective image file with the correct AP image location. The corresponding metadata file is also updated with the new AP model capability information.

If a new AP model belongs to a new AP model family and requires a new image file, create a new image entry file in the correct AP image location. The corresponding metadata file is updated with the new AP model capability information.

> **Note**
>
> The APDP images must not be renamed to prevent impact on its functionality.

Install AP device package (GUI)

Install AP device package using GUI.

Add or upgrade AP device support in your network.

Procedure

1. Choose **Administration** > **Software Management**.
2. Click **AP Device Package (APDP)** tab.
3. Click **Add**.
4. From the **Transport Type** drop-down list, select the transfer type to transfer the software image to your device as TFTP, SFTP, FTP, Device, or Desktop (HTTP).
   a) If you choose **TFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **File path** and select a **File System** from the drop-down list.
   b) If you choose **SFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path** and select a **File System** from the drop-down list.
   c) If you choose **FTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and select a **File System** from the drop-down list.
   d) If you choose **Device** as the **Transport Type**, enter the **File path** and select a **File System** from the drop-down list.
   e) If you choose **Desktop (HTTPS)** as the **Transport Type**, select a **File System** from the drop-down list.
   f) Click **Select File** to navigate to the **Source File Path**.
5. Enter the **File Name** and click **Add File**.
6. From the **AP Upgrade Configuration** section, select the percentage of APs to be included from the **AP Upgrade per iteration** drop-down list.
7. Click **Apply**.

Install AP device package (CLI)

Install AP device package using commands.

Install and activate new AP device packages on the controller using the CLI.

Procedure

1. Extract AP images from APDP and place them in SMU or APDP specific mount location.

   Example

   ```
   Device# install add file bootflash filename
   ```

> **Note**
>
> Here, the SMU does not trigger the Wireless module.

2. Add the AP software in APDP to the existing current active AP image list.

   Example

   ```
   Device# install activate file bootflash filename
   ```

   Also, update the capability information for the new AP models in the controller .

   > **Note**
   >
   > Even if the new AP module supports new hardware capabilities, the controller recognizes only the capability information that its base version supports.

   At this point, the controller accepts the new connection from the new AP model. The new AP model then joins the controller .

3. Commit the new AP software to be persistent across reloads.

   Example

   ```
   Device# install commit
   ```

   The commit occurs after activation when the system is up, or after the first reload. If a package is activated but not committed, it remains active after the first reload but becomes inactive after the second reload.

4. (Optional) Deactivate an active APDP, update the package status, and trigger a process to restart or reload.

   Example

   ```
   Device# install deactivate file bootflash filename
   ```

5. Display the image version on the device.

   Example

   ```
   Device# show version
   ```

Verify APDP on the Controller

Verify the status of APDP packages on the controller and the embedded wireless controller.

To verify the status of APDP packages on the controller , use the command:

```
Device# show install summary

[ Chassis 1 ] Installed Package(s) Information:
State (St): I - Inactive, U - Activated & Uncommitted, C - Activated &
Committed, D - Deactivated & Uncommitted
--------------------------------------------------------------------------------
Type  St   Filename/Version
--------------------------------------------------------------------------------
APDP  I    bootflash:apdp_CSCvp12345.bin
IMG   C    17.1.0.0
--------------------------------------------------------------------------------
Auto abort timer: inactive
--------------------------------------------------------------------------------
```

Note

The output of this command varies based on the packages, and the package states that are installed.

Per site or per AP model service pack (APSP)

Explains per site or per AP model service packs (APSPs) as targeted software maintenance updates for access points, enabling administrators to control and tailor update deployment by site or device model.

A per-site and per-AP model service pack is a software maintenance update option that:

- allows administrators to roll out critical AP updates and bug fixes to subsets of APs at specific sites or to particular AP models
- enables staggered and targeted deployment (by site or AP model) to control the propagation of a SMU in your network by selecting which sites to include in the SMU activation.
- integrates with FlexConnect, local mode, and SD-Access wireless deployments for selective upgrade strategies.

Ensure all sites are at the same SMU level before you roll out a new SMU to selected sites or start an image upgrade on the system.

With per-AP model SMU, you can update only specific AP models. The software downloads and activates only on chosen AP models at a site. If you include specific model images in a SMU, you must also include software images for those models in future updates.

Note

After you apply the AP site filter for a per-site SMU upgrade, install a new image only if you have applied the site filter to all sites, or if you have removed the current site filter.

Restrictions and workflow

Restrictions for configuring APs to a primary controller

- If you do not configure APs to a primary controller, all APs receive the same discovery response from controllers with and without the APSP image. This causes your APs to switch repeatedly between two controllers.

Workflow of AP SMU Upgrade

- To upgrade the AP SMU, run a query to check for ongoing activities, such as AP image predownload or AP rolling upgrade.
- Identify the sites for SMU installation and set up a site filter.
- Trigger the SMU predownload for the sites in the site filter.
- Activate the SMU after the predownload completes.
- Commit the update.

Note

After you set up the site filter, you can add more sites. To make your changes take effect, apply the filter again using the **ap image site-filter file** *file-name* **apply** command. If you clear the site filter, updates are applied to all remaining sites. When you deactivate or roll back images, the action is applied to all sites, not just filtered sites.

Rolling AP upgrade

Rolling AP upgrade details.

A rolling AP upgrade is an upgrade method that

- updates APs in staggered batches such that some APs are always up in the network and provide seamless coverage to clients while the other APs are selected to be upgraded, and
- requires preloading the image in advance to ensure that all APs scheduled for upgrade have the new version.

Note

The time needed to complete a rolling AP upgrade depends on several factors: the number of APs, the percentage in each iteration, the controller type, and the controller's connectivity to the APs. To estimate the upgrade time, multiply the number of iterations by the maximum iteration time. Each iteration can take up to 5 minutes multiplied by the expected number of iterations. You can view the end time by checking the **iteration expiry time** field in the **show ap upgrade** command.

Rolling AP upgrade process

Rolling AP upgrade process.

Rolling AP upgrade is done on a per controller basis. The number of APs to be upgraded at a given time is a percentage of the total number of APs connected to the controller. The percentage is capped at a user configured value. The default percentage is 15. Upgrade all non-client APs before upgrading any client APs.

The key components involved in the process are:

- Controller
- APs
- Clients

The process involves the following stages:

1. Candidate AP set selection:

   In this stage, a set of AP candidates is selected based on neighboring AP information. For example, if you identify an AP for upgrade, a certain number (N) of its neighbors are excluded from candidate selection. The N values are generated in the following manner:

   If the user configurable capped percentage is 25%, then N=6 (Expected number of iterations =5)

   If the user configurable capped percentage is 15%, then N=12 (Expected number of iterations=12)

   If the user configurable capped percentage is 5%, then N=24 (Expected number of iterations =22)

   If you cannot select candidates using neighboring AP information, select candidates from indirect neighbors. If this still fails, the AP is upgraded without failure.

   Note

   If you have more candidate APs than the configured percentage allows, remove the extra candidates to maintain the percentage cap.

2. Client steering:

   Move clients connected to candidate APs to other APs before rebooting the candidate APs. Each AP sends a request to its associated clients, providing a list of the best available APs (excluding candidate APs). The system marks candidate APs as unavailable for neighbor lists and resets these markings during the AP rejoin and reload process.

3. AP rejoin and reload process:

   After steering clients, if any clients remain connected to the candidate AP, de-authorize those clients and reload the AP so it restarts with a new image. Set a three-minute timer for the APs to rejoin. When the timer expires, check if all candidate APs have joined the controller or mobility peer. If 90% have joined, end the iteration. If not, extend the timer by three minutes and check again. After three attempts, start the next iteration. Each iteration usually lasts about 10 minutes.

   You only need to configure the number of APs to upgrade at a time as a percentage of the total APs in the network. The default is 15 percent.

```
Device(config)# ap upgrade staggered {25 | 15 | 5}
```

Use the command to trigger the rolling AP upgrade:

```
Device# ap image upgrade [test]
```

Note

Rolling AP upgrade does not resume after an SSO. To restart it, use the **ap image upgrade** command. This restarts the upgrade for all APs, including Mesh APs.

Install AP service package (GUI)

Install AP service package using GUI.

Use the GUI to install a new or updated AP service package on your device when needed.

Before you begin

Procedure

1. Choose **Administration** > **Software Management**.
2. Click the **AP Service Package (APSP)** tab.
3. Click **Add**.
4. From the **Transport Type** drop-down list, choose the transfer type to transfer the software image to your device as TFTP, SFTP, FTP, Device, or Desktop (HTTP).
   a) If you choose **TFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **File path**, and select **File System** from the drop-down list.
   b) If you choose **SFTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **SFTP Username**, **SFTP Password**, **File path**, and select **File System** from the drop-down list.
   c) If you choose **FTP** as the **Transport Type**, enter the **Server IP Address (IPv4/IPv6)**, **FTP Username**, **FTP Password**, **File path**, and select **File System** from the drop-down list.
   d) If you choose **Device** as the **Transport Type**, enter the **File path** and select **File System** from the drop-down list.
   e) If you choose **Desktop (HTTPS)** as the **Transport Type**, select **File System** from the drop-down list, and click **Select File** to navigate to the **Source File Path**.
5. Enter the **File Name** and click **Add File**.
6. From the **AP Upgrade Configuration** section, select the percentage of APs to include from the **AP Upgrade per iteration** drop-down list.
7. Click **Apply**.

Install AP service package (CLI)

Install AP service package using commands.

Use this procedure to selectively update APs with SMU. Apply image updates only to APs that are filtered by site tags using CLI.

Procedure

1. Check for ongoing activities such as AP image predownload or AP rolling upgrade.

   Example

   ```
   Device# install add file flash filename
   ```

   If there are no such activities, populate the predownload directory to install a package file to the system.

2. Add a site tag to a site filter.

   Example

   ```
   Device# ap image site-filter file filename flash add site-tag bgl18
   ```

3. Optional: Remove a site tag from a site filter.

Example

```
Device# ap image site-filter file filename flash remove site-tag bgl18
```

4. Optional: Perform predownload of an AP image.

   Example

   ```
   Device# ap image predownload
   ```

   This image predownload is filtered by the site filter, set up in the previous step.

5. Trigger the AP upgrade in a rolling, staggered fashion for the APs added in the site filter.

   Example

   ```
   Device# install activate file filename flash
   ```

6. Commit the image update.

   Example

   ```
   Device# install commit
   ```

   During the commit, the mapping from file to site is saved in the persistent database. This ensures the mapping remains available after a reload.

Add a site to a filter (CLI)

Add a site to a filter using commands.

Add a site tag to a site filter to control which APs receive image pre-downloads and upgrades.

Procedure

1. Add a site tag to a site filter.

   Example

   ```
   Device# ap image site-filter file filename flash add site-tag bgl18
   ```

2. Predownload the image and upgrade the APs based on the site filter.

   Example

   ```
   Device# ap image site-filter file filename flash apply
   ```

3. Clear the site filter table, predownload the image, and perform a rolling AP upgrade to all sites where it is not active.

Example

```
Device# ap image site-filter file flash filename clear
```

Deactivate an image (CLI)

Deactivate an image using commands.

Remove or deactivate a specific AP image from all sites using CLI.

Procedure

Perform rolling AP upgrade based on the AP models present in the prepare file.

Example

```
Device# install deactivate file flash filename
```

Deactivation is not limited by site and applies to all sites.

> **Note**
>
> The system takes action only if the APs in a site are not running the SMU that is being deactivated.

Roll back APSP (CLI)

Roll back APSP using commands.

Revert AP images to a previous software state by using rollback profiles and image predownload support.

Procedure

1. Optional: Move to any rollback point using AP image predownload support.

   Example

   ```
   Device# install add profile rollback_profile-name rollback_id1
   ```

   > **Note**
   >
   > To get a list of available rollback profile names, use the **show install profile** command.

2. Optional: Perform predownload of an AP image.

Example

```
Device# ap image predownload
```

This image predownload is filtered by the site filter, which you set up earlier.

3. Perform rollback of the image for the affected AP models.

Example

```
Device# install rollback to rollback_id rollback_id1
```

The roll back action is not filtered by site. Therefore, rollback applies to all the sites.

> **Note**
>
> APs that are in the base image, or at a point before the rollback action takes effect, are not affected.

Cancel the Upgrade (CLI)

Cancel the upgrade using commands.

Stop an in-progress or pending software upgrade on your device using CLI.

Procedure

Abort the upgrade by resetting the APs in a rolling fashion.

Example

```
Device# install abort
```

Verify the upgrade

Verify the upgrade using commands.

To see the summary of the AP software install files, enter the command:

```
Device# show ap image file summary

16 Efficient Image Upgrade and Out-of-band AP Image Download

Topics:

- Efficient image upgrades for FlexConnect APs
- Out-of-band AP image download

Efficient image upgrades for FlexConnect APs

Introduces Efficient Image Upgrade capabilities, outlining restrictions, the image upgrade download process, and instructions for enabling pre-download through the GUI to streamline wireless network software updates.

Efficient image upgrade is an optimized upgrade method for FlexConnect APs that

- reduces WAN link load by limiting simultaneous image downloads to three secondary APs per primary AP.
- allows simultaneous secondary AP downloads from a designated primary AP, and
- enables faster image pre-downloads for FlexConnect APs.

Feature History

Release	Feature	Feature Information
Cisco IOS XE 17.11.1	Out-of-Band AP Image Download	This feature enhances the AP image upgrade method to make upgrades faster and more flexible. Commands Introduced: • **ap upgrade method https** • **ap file-transfer https port** • **show ap upgrade method**

Analogy: relay race

Efficient image upgrades work like a relay race for file sharing. Imagine a group of runners (APs) at a remote location needing a baton (the software image) from the main building (the controller). Instead of each runner making the trip directly and crowding the hallway (the WAN link), one designated runner (the primary AP) gets the baton first and brings it back. The others then take the baton from this runner in controlled small groups (three at a time), so the hallway never gets overcrowded, saving time and reducing congestion.

Restrictions

- Efficient image upgrades work only in FlexConnect (flex mode).
- Ensure all FlexConnect APs are grouped under the same site tag, and are physically co-located.
- Efficient image upgrades do not operate when the default-site-tag is applied.
- You cannot remove flex profile configurations from a site tag that is configured as a site.
- Use the **no local-site** command to prepare a site tag for Flexconnect. Otherwise, the Flex profile configuration is not applied.
- Efficient AP image download uses port 8443 for HTTPS connections. The listener also uses this port to upload client debug bundles and transfer Clean Air spectral recordings from the AP to the controller. This port remains open even if you disable efficient AP image download because multiple services use it.

Efficient image upgrade download

Efficient AP image download minimizes WAN load, accelerates image distribution for co-located FlexConnect APs, and ensures reliable and consistent image deployment within site tags.

Summary

The key components involved in the process are:

- **Controller**: Hosts and distributes AP images through WAN.
- **Primary AP**: Selected for each model per site tag to fetch the image from the controller.
- **Secondary APs**: Retrieve the image from the primary AP through TFTP. Up to three secondary APs can download simultaneously.

Workflow

These stages describe the efficient AP image download:

1. The controller selects one AP per model and site tag as the primary AP.
2. The primary AP downloads the required image directly from the controller over WAN.
3. Up to three secondary APs download the image simultaneously through TFTP from the primary AP. This approach minimizes WAN usage.
4. The process uses port 8443 for HTTPS connections. This port is also used for uploading debug bundles and spectral recordings.
5. The port remains open, as multiple services use this listener even if efficient AP image download is disabled.

Result

Efficient AP image download minimizes WAN load, accelerates image distribution for co-located FlexConnect APs, and ensures consistent, reliable image deployment within site tags.

Enable pre-download in a FlexConnect AP (GUI)

Enable Pre-Download using GUI.

Allow access points to download software images in advance to minimize downtime during upgrades.

Use this task when you want APs to pre-download image updates through the GUI.

Follow these steps to enable pre-download for an AP:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Access Points** window, expand the **All Access Points** section and click the name of the AP to edit.
3. In the **Edit AP** window, click the **Advanced** tab and from the **AP Image Management** section, click **Predownload**.
4. Click **Update & Apply to Device**.

The selected AP downloads the software image in advance, reducing downtime during the upgrade process.

Configure an efficient image upgrade for FlexConnect APs

To configure pre-download, you must complete the described series of tasks:

1. Create a flex profile using the CLI and enable pre-download. You can also use an existing flex profile. See *Enable pre-download in a flex profile (CLI)*.
2. Configure a site tag. Site tags group APs and apply common settings, such as the flex profile you created in the previous task. See *Configure a site tag for FlexConnect APs (CLI)*.

3. Attach the policy tag and site tag to the AP. This task configures APs with the correct policy and site tag. See *Attach policy tag and site tag to an AP (CLI).*
4. Trigger pre-download for a site tag to start the image pre-download to the APs associated with the site tag. You can then verify the pre-download status. See *Trigger and verify pre-download to a site tag*.

Configure a flex profile for pre-download (CLI)

Enable Pre-Download using commands.

Enable image pre-downloading for remote APs in a FlexConnect flex profile from the CLI.

Use this task to pre-download software images on APs associated with a flex profile. This accelerates upgrade rollouts and reduces network downtime.

Before you begin

- Identify the target flex profile to be updated.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a flex profile and enter the flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex rr-xyz-flex-profile
   ```

3. Enable pre-download of the image.

   Example

   ```
   Device(config-wireless-flex-profile)# predownload
   ```

4. Exit the configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

Pre-download is enabled for the selected flex profile. APs in this profile download the image before upgrades.

What to do next

Monitor AP status to verify successful pre-download before scheduling the upgrade.

Configure a site tag for FlexConnect APs (CLI)

Configure a Site Tag using CLI.

Set up a site tag for wireless deployments to enable site-specific configurations using the CLI.

Before you begin

Gather required information, such as the desired site tag name and flex profile name.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a site tag and enter site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site rr-xyz-site
   ```

3. Configure a flex profile.

   Example

   ```
   Device(config-site-tag)# flex-profile rr-xyz-flex-profile
   ```

   - You cannot remove flex profile configurations from a site tag that is configured as a local site.

     Use the **no local-site** command to remove local site configurations before applying flex profile configurations.

4. Add a description for the site tag.

   Example

   ```
   Device(config-site-tag)# description "default site tag"
   ```

5. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-site-tag)# end
   ```

6. Optional: Display the number of site tags.

   Example

   ```
   Device# show wireless tag site summary
   ```

The site tag is configured on the device, and site-specific settings are applied.

Verify site tag configuration

Verify the site tag configuration:

- To view detailed information about a site, use the **show wireless tag site detailed** *site-tag-name* command.
- To view default tag (site-tag) type when both site tag and policy tag are not configured, use the output of the **show wireless loadbalance tag affinity wncd** *wncd-instance-number* command.

Attach policy tag and site tag to an AP (CLI)

Attach Policy Tag and Site Tag to an AP using commands.

Assign a policy tag and site tag to an AP using the CLI.

Use this procedure to associate specific network policies and locations with an AP in your Cisco wireless deployment.

Before you begin

Make sure you have the wired MAC address of the AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco AP and enters AP profile configuration mode.

   Example

   ```
   Device(config)# ap F866.F267.7DFB
   ```

   > **Note**
   >
   > The *mac-address* should be a wired mac address.

3. Map a policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag rr-xyz-policy-tag
   ```

4. Map a site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag rr-xyz-site
   ```

5. Associate the RF tag.

Example

```
Device(config-ap-tag)# rf-tag rf-tag1
```

6. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

7. Optional: Display AP details and the tags associated to it.

Example

```
Device# show ap tag summary
```

8. Display the AP name with tag information.

Example

```
Device# show ap name "ap-name" tag info
```

9. Optional: Display the AP name with tag details.

Example

```
Device# show ap name ap-name tag detail
```

The AP is now associated with the specified policy, site, and optionally, RF tags you selected

Trigger and verify pre-download to a site tag

Trigger Predownload to a Site Tag using commands.

Start and confirm an image pre-download for a specific site tag by using CLI

Use this task to distribute a new software image to primary and secondary APs in advance of a full deployment.

Before you begin

Identify the site tag to which you want to pre-download the image.

Procedure

---

1. Enter the privileged EXEC mode.

Example

```
Device> configure terminal
```

2. Instruct the primary APs to start image predownload.

Example

```
Device# ap image predownload site-tag rr-xyz-site start
```

3. Display the list of primary APs per AP model per site tag.

Example

```
Device# show ap primary list
```

4. Display the pre-downloading state of primary and secondary APs.

Example

```
Device# show ap image
```

> **Note**
>
> To check if efficient image upgrade is enabled in the AP, use the **show capwap client rcb** command on the AP console.

Example

The output displays the primary AP.

```
Device# show ap primary list
AP Name                          WTP Mac           AP Model           Site Tag

-------------------------------------------------------------------------------------
AP0896.AD9D.3124                 f80b.cb20.2460    AIR-AP2802I-D-K9 ST1
```

The output shows that the primary AP has started pre-downloading the image.

```
Device# show ap image
Total number of APs: 6

Out-of-band AP image download

Explains the out-of-band access point image download process, including key concepts and implementation details for managing AP firmware updates independently of the primary network connection.

Out-of-band AP image download is an enhanced upgrade method that

- moves AP image downloads out of the CAPWAP control path using an enhanced webserver (nginx) on the controller
- improves upgrade speed and flexibility compared to traditional in-band methods, and
- falls back to CAPWAP method automatically if the out-of-band download fails.

Out-of-band download advantages

In WLAN deployments, APs traditionally gather their software image and configuration from the controller (in-band) during the join, predownload, and upgrade phases over the CAPWAP control path. This mechanism has limitations in the context of CAPWAP window size, processing of CAPWAP packets, and parallel image downloads. With image upgrade being a significant activity in the lifecycle of APs, upgrades become a time-consuming activity when the deployment size increases, especially for remote deployments, because the image always comes from the controller, irrespective of the deployment types.

To make upgrades faster and more flexible, the AP image upgrade method is enhanced in Cisco IOS XE Dublin 17.11.1 release. An enhanced webserver (nginx) running on the controller helps the AP image downloads to be available out of the CAPWAP path (out of band).

Key considerations for out-of-band AP image download:

- HTTPS configuration done at the global level applies to all the APs joining the controller.
- When AP image download over an Out-of-Band method fails, the download falls back to the CAPWAP method, as a result of which the APs will not be stranded.
- AP image download over HTTPS may fail if the HTTPS server Trustpoint has a chain of CA certificates.
- Before you downgrade from Cisco IOS XE Dublin 17.11.1 to an earlier version, ensure that the Out-of-Band AP Image Download feature is disabled, as it is not supported in previous releases.

Feature history for out-of-band AP image download

Lists release and related information for out-of-band AP image download feature.

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one in which it is introduced in, unless noted otherwise.

Table 20: Feature history for out-of-band AP image download

Feature	Release	Feature Information
Out-of-Band AP Image Download	Cisco IOS XE Dublin 17.11.1	The AP image upgrade method is enhanced to make the upgrades faster and more flexible.

Restrictions for Out-of-Band AP image download

Outlines platform restrictions for Out-of-Band AP Image Download feature.

This feature is not supported on the following platforms:

- Cisco Embedded Wireless Controller on Catalyst Access Points
- Cisco Embedded Wireless Controller on Catalyst Switches
- Cisco Wave 1 Access Points

Download AP image from controller using HTTPS (CLI)

Configure AP image download from the controller using HTTPS using commands.

Configure APs to download images from the controller over HTTPS for efficient out-of-band image updates.

APs can download images efficiently from the controller using HTTPS when the AP supports out-of-band download methods. This feature reduces upgrade time and network overhead compared to traditional CAPWAP-based image transfers.

Before you begin

- HTTPS configuration must be enabled.
- The nginx server must be running on the controller. Use the **show platform software yang-management process** command to check whether the nginx server is running.
- The custom-configured port must be reachable between the controller and the corresponding AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the corresponding AP to download the image over HTTPS from the controller.

   Example

   ```
   Device(config)# ap upgrade method https
   ```

   This command configures the AP to use out-of-band AP image download method if the AP supports it.

   You can check whether the AP supports efficient download method using the **show AP config general** command.

   Use the **no** form of this command to disable out-of-band AP image download method.

3. Configure a custom port for image download from the nginx server running on the controller.

   Example

   ```
   Device(config)# ap file-transfer https port port-number
   ```

   Example

   ```
   Device(config)# ap file-transfer https port 8445
   ```

   For HTTPS port, the valid values range from 0 to 65535, with a default of 8443. You cannot use port 443 for AP file transfers because it is the default port used for other HTTPS requests. Also, avoid configuring standard and well-known ports because the configuration may fail.

   By default, the Efficient AP image download feature uses port 8443 for HTTPS. If the same port is configured for HTTPS access for controller GUI, then GUI access will not work. In such instances, use a port number other than 8443 for controller GUI Access or configure a different port for AP file transfer over HTTPS instead of 8443.

   The port 8443 is customizable. A sample config is given below:

   ```
   Source= wireless controller
   Destination= Access Point
   Protocol=HTTPS
   Destination Port=8443
   Source Port=any
   Description= "Out of Band AP Image Download"
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The AP is now configured to download images from the controller using HTTPS over the specified port, enabling efficient out-of-band image updates.

Download AP Image from Controller Using HTTPS (GUI)

Configure AP image download from the Controller using HTTPS through the GUI interface.

Enable efficient AP image upgrade by configuring HTTPS method for out-of-band file transfer from the controller to access points.

The HTTPS method provides an efficient out-of-band file transfer mechanism for AP image upgrades. This configuration allows access points to download images directly from the controller using HTTPS protocol on a designated port.

Procedure

---

1. Choose **Configuration > Wireless > Wireless Global**.
2. In the **AP Image Upgrade** section, enable the **HTTPS Method** to allow image download on APs from the controller, over HTTPS.

> **Note**
>
> The AP should support out-of-band image download. You can verify this in the **Configuration > Wireless > Access Points** window. Select the AP, and in the **Edit AP > Advanced** tab, view the details of the support in the **AP Image Management** section.

3. Enter the **HTTPS Port** to designate AP file transfers on that port.

   Valid values range from 0 to 65535, with the default being 8443. Note that you cannot use port 443 for AP file transfers because that is the default port for other HTTPS requests.

   By default, the Efficient AP image download feature uses port 8443 for HTTPS. If the same port is configured for HTTPS access for controller GUI, then GUI access will not work. In such instances, use a port number other than 8443 for controller GUI Access or configure a different port for AP file transfer over HTTPS instead of 8443.

4. Click **Apply to Device** to save the configuration.

The HTTPS method for AP image download is now enabled and configured. Access points that support out-of-band image download can now efficiently download images from the controller using the specified HTTPS port.

Verify image upgrade

Provides verification commands for out of band image download status and methods.

Verify out of band image download capabilities, status, and methods used by access points for image upgrades.

To check whether an AP supports efficient download method, use this command:

```
Device# show ap config general

Cisco AP Name : AP002C.C862.E880
=================================================

Cisco AP Identifier : 002c.c88b.0300
Country Code : Multiple Countries : IN,US
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-ABDN
AP Country Code : US - United States
AP Regulatory Domain
802.11bg : -A
AP Upgrade Out-Of-Band Capability : Enabled
AP statistics : Disabled
```

To view the AP image download statistics, use this command.

Use the **show AP image** command to see the detailed output.

```
Device# show ap image summary

Total number of APs  : 1
Number of APs
        Initiated                 : 0
        Downloading               : 0
        Predownloading            : 0
        Completed downloading     : 0
        Completed predownloading  : 0
```

```
        Not Supported              : 0
        Failed to Predownload      : 0
        Predownload in progress    : No
```

To view the method used to download the AP image, use this command:

```
Device# show wireless stats ap image-download

AP image download info for last attempt
AP Name  Count ImageSize StartTime         EndTime            Diff(secs)
Predownload Aborted  Method
-------------------------------------------------------------------------------------------
mysore1  1     40509440  08/23/21 22:17:59 08/23/21 22:19:06  67         No
        No       CAPWAP
```

To view the method used to download the AP image, use this command:

```
Device# show ap upgrade method

AP upgrade method HTTPS : Disabled
```

To view the port used for the AP image transfer, use this command:

```
Device# show ap file-transfer https summary

       Configured port                : 8443
       Operational port               : 8443

!If different ports are shown under 'Configured port' and 'Operations port'
!that means custom port configuration has failed and is continuing with the
previous port.
!The failure reason could be the input port, which is a well-known port and
already in use.
```

To view the whether an AP supports image download over HTTPS, use this command:

```
Device# show ap name AP2800 config general | sec Upgrade

AP Upgrade Out-Of-Band Capability               : Enabled
```

To view the detailed output an AP's pre-image, use this command:

```
Device# show ap image

Total number of APs  : 2
Number of APs
        Initiated                  : 0
        Downloading                : 0
        Predownloading             : 0
        Completed downloading      : 2
        Completed predownloading   : 0
        Not Supported              : 0
        Failed to Predownload      : 0
```

```
        Predownload in progress    : No
AP Name    Primary Image Backup Image Predownload Status Predownload Version

!The 'method' column indicates the download method used by the AP.
```

17 Predownloading an Image to an Access Point

Topics:

- Image pre-downloads to AP
- AP image download time enhancement

Image pre-downloads to AP

Introduces AP image pre-download concepts, detailing feature history and outlining restrictions that impact image deployment to access points on controllers.

An image pre-download is a software distribution process that

- downloads an upgrade image to an AP from the device,
- minimizes network outages and allows continuous connectivity during the image download process, and
- ensures the AP can join and register with the controller immediately after the upgrade.

Additional reference information

Previously, you could download an upgrade image to the device and reset it. This AP then entered discovery mode. After discovering the controller with the new image, the AP downloads the new image, resets itself, enters discovery mode, and rejoins the device.

You can now download the upgrade image to the controller. When the controller is operational with the upgrade image, the AP joins the controller and moves to **Registered** state, because the AP image has been predownloaded to the AP.

Feature history for AP pre-download

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 21: Feature history for AP pre-download

Release	Feature Information
Cisco IOS XE Bengaluru 17.5.x	This feature now has GUI and YAML support. For more information, see the Programmability Configuration Guide, Cisco IOS XE Bengaluru 17.5.x.
Cisco IOS XE Gibraltar 16.11.1	This feature minimizes network outages, downloads an upgrade image to an access point from the device without resetting the access point or losing network connectivity. This feature has CLI support only.

Restrictions and best practices for pre-downloading an image to an AP

Restrictions for pre-downloading an image to an AP.

Restrictions

- You can pre-download images for up to 100 APs per Wireless Network Control Daemon (WNCD) instance on the controller when using the default CAPWAP method, and up to 50 APs per WNCD instance when using the HTTPS upgrade method. For the Catalyst 9800-L model, image pre-download is limited to 25 APs per WNCD instance for CAPWAP method.

  The controller initiates pre-download requests periodically until the maximum number of APs allowed for that interval is reached. The trigger interval is every ten seconds for CAPWAP-based upgrades and every one second for HTTPS-based upgrades.

- If an AP has only 16 MB total available memory, it may not have enough free memory to download an upgrade image. To free up space, the AP may automatically delete crash information files, radio files, and backup images. Pre-downloading is not affected because the pre-download image replaces any backup images on the AP.
- Ensure that all primary, secondary, and tertiary controllers run the same images. If the images differ, the feature does not work.
- Each AP can store only two software images.
- The controller supports only self-signed certificates and does not support Cisco certificates. If AP join fails after you move APs between controllers, run the **capwap ap erase all** command to remove the hash string from the APs.
- If the latest upgrade image is already on the AP, pre-download is not triggered. Check whether the primary and backup image versions are the same as the upgrade image, using the **show ap image** command.

Known behavior

- Predownload of the AP image is based on the AP model rather than the image type.
- If an AP remains in the predownloading state after an SSO event, enter:
  - **ap image predownload abort**
  - **clear ap predownload stats**
- When you upgrade Cisco Wave 1 APs from Cisco AireOS Release 8.3 to Cisco IOS XE Gibraltar 16.10.1, the AP may download the image twice. This can increase downtime during migration.

Best Practices

- Before you reset the controller, ensure all APs have completed downloading the image.
- To view cumulative statistics about AP images in the controller, you must first use the **clear ap predownload statistics** command to clear the statistics and ensure that the correct data is displayed. Then, use the **show ap image** command to view cumulative statistics about AP images in the controller,
- During AP image pre-download, the WNCD CPU may reach 99 percent. This is normal and does not cause crashes or disconnect problems for clients or APs.

Procedures

Provides step-by-step procedures for predowloading images to access points using CLI, GUI, and YANG interfaces, and explains monitoring of the pre-download process to ensure deployment success.

Pre-download an image to AP (CLI)

Pre-download an Image to Access Points using commands.

Minimize downtime during controller upgrades by pre-downloading and activating a new software image on connected APs.

Use this task if you want to push an image to APs before an upgrade, minimizing downtime during switchover.

For more information, see this video.

Before you begin

- Ensure the controller is in install mode.

- Confirm the AP model exists in the new capability XML file on the controller and maintained internally in the controller. With the appropriate modification of the capability XML through a controller upgrade, APSP, or APDP installation, the controller can override the existing AP image for a particular model.
- Copy the new image either from the TFTP server, flash image, or USB.

Procedure

1. Add and expand the controller software image.

   Example

   ```
   Device# install add file bootflash:image.bin
   ```

2. Download the new image to all the APs or a specific AP connected to the device.

   Example

   ```
   Device# ap image predownload
   Device# ap name ap1 image predownload
   ```

3. Verify the AP's pre-download status.

   Example

   ```
   Device# show ap image
   ```

   This command initially displays the status as Predownloading and then moves to Completed, when download is complete.

4. Display image details of a particular AP.

   Example

   ```
   Device# show ap name myapname image
   ```

5. Swap images of the APs that have completed pre-download.

   Example

   ```
   Device# ap image swap
   ```

   ```
   Device# ap name myapname image swap
   ```

   ```
   Device# ap image swap completed
   ```

> **Note**
>
> You can swap the AP images using **ap image swap** command even without pre-downloading a new image to the AP and there are no restrictions or prerequisites to swap the image.

6. Run compatibility checks, install the package, and update the package status details

   Example

   ```
   Device# install activate
   ```

   For restartable packages, the command triggers the appropriate post-install scripts to restart the necessary processes,

   For non-restartable packages, the command triggers a reload.

   > **Note**
   >
   > This step reloads the complete controller stack. If HA is used, both primary and secondary controllers.

7. Commit the activation changes to be persistent across reloads.

   Example

   ```
   Device# install commit
   ```

   .

   The commit can be done after activation while the system is up, or after the first reload. If the package is activated but not committed, it remains active after the first reload, but not after the second reload.

The new software image is downloaded and activated on all designated APs

What to do next

Monitor AP connectivity and operation to confirm successful upgrade.

Abort AP pre-download (CLI)

Abort an AP image pre-download using CLI commands.

Stop an AP image pre-download that is in progress.

Use this task when you need to stop an AP image pre-download before it completes.

Before you begin

- Ensure that you have access to privileged EXEC mode.

- Use the **show ap image** command to verify the AP image pre-download status.

Procedure

1. Verify the AP image pre-download status.

   Example

   ```
   Device# show ap image
   ```

   Verify that one or more access points have a pre-download status of **Predownloading**.

2. Abort the AP image pre-download.

   Example

   ```
   Device# ap image predownload abort
   ```

   > **Note**
   >
   > This command stops the current AP image pre-download operation. It does not reboot the access points or swap their images.

3. Verify the AP image status after aborting the pre-download.

   Example

   ```
   Device# show ap image
   ```

   Verify that the access points are no longer in the **Predownloading** state.

4. If you need to initiate another pre-download, clear the pre-download state and start the pre-download again.

   Example

   ```
   Device# clear ap predownload stats
   Device# ap image predownload
   ```

   > **Note**
   >
   > Run **clear ap predownload stats** only when you need to initiate another pre-download after aborting the current operation.

The AP image pre-download is aborted.

What to do next

To cancel an AP image upgrade, use the **ap image upgrade abort** command instead.

Pre-download an image to AP (GUI)

Pre-download an Image to Access Points using GUI.

Before you begin

- Ensure the Upgrade mode of the controller is in install mode.

You can minimize downtime during controller upgrades by pre-downloading and activating a new software image on connected APs using the connector GUI.

You can also see the video demonstration.

Procedure

1. Choose **Administration** > **Software Management** and click the **Software Upgrade** .
2. Set necessary parameters:
   a) Select a **Transport Type**.
   b) Select a **File Path**.
   c) Select **Source File Path**.
3. Check the **AP Image Predownload** check box.

   If you already have an inactive image file on your device, a dialog box prompts you to remove the unused image and proceed with the latest image download.
4. Click **Download and Install** to initiate the upgrade process.

   You can view and verify the pre-download progress in the **Status** dialog box. You can also check the progress log by clicking the **Show Logs** icon.
5. When the pre-download is completed, click **Save Configuration and Activate**.
6. Click **Yes** to confirm the activation.

   This step runs compatibility checks, installs the package, and updates the package status details. After a successful activation, the AP reloads. If there are uncommitted files, the system prompts you to remove those.
7. Click **Commit** to complete the upgrade process.

The new image is pre-downloaded, and activated on the APs. The APs reload with upgraded software.

Pre-download an image to AP (YANG)

Prepare an AP for a software upgrade or deployment by pre-downloading an image using YANG automation.

Use YANG with NETCONF and RESTCONF to automate and program network operations

Procedure

Send the NETCONF remote procedure call (RPC) call using your management client to initiate the image pre-download. Replace `<uuid>` with the correct value for your environment

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="101">
  <set-rad-predownload-all
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-access-point-cmd-rpc">
    <uuid>12312341231234</uuid>
  </set-rad-predownload-all>
</rpc>
```

The image is pre-downloaded to the access point, making it available for upgrade or installation.

What to do next

Refer to the Cisco IOS XE Programmability Configuration Guide and YANG Data Models on Github website for more details.

Contact the Developer Support Community for NETCONF or YANG features.

Monitor AP pre-download

Monitor the AP Pre-download from controller.

This section describes the commands for monitoring AP pre-download from the controller.

Verify the AP pre-download status and progress from the controller:

```
        Controller# show ap image
        Total number of APs  : 1

        Number of APs
        Initiated                   : 1
        Predownloading              : 1
        Completed predownloading    : 0
        Not Supported               : 0
        Failed to Predownload       : 0

        AP Name                           Primary Image   Backup Image
Predownload Status    Predownload Ver...  Next Retry Time    Retry Count

---------------------------------------------------------------------------------------------------

        AP1                               10.0.1.66       10.0.1.66
Predownloading        10.0.1.67           NA                          0
```

```
        Controller# show ap image

        Total number of APs  : 1

        Number of APs
        Initiated                   : 1
        Predownloading              : 0
```

```
        Completed predownloading   : 1
        Not Supported              : 0
        Failed to Predownload      : 0

        AP Name                            Primary Image   Backup Image
Predownload Status    Predownload Ver...  Next Retry Time    Retry Count

------------------------------------------------------------------------------------------------------

        AP1                                10.0.1.66       10.0.1.67
Complete              10.0.1.67           NA
        0
```

Verify the image details of a particular AP:

```
        Controller# show ap name APe4aa.5dd1.99b0 image

        AP Name : APe4aa.5dd1.99b0
        Primary Image : 10.0.1.66
        Backup Image : 10.0.1.67
        Predownload Status : None
        Predownload Version : 000.000.000.000
        Next Retry Time : N/A
        Retry Count : 0
```

AP image download time enhancement

Describes AP Image Download Time Enhancement for OEAP or Teleworker deployments.

AP image download time enhancement is a feature that

- adds support to multiple sliding windows for control packets going from controller to AP
- reduces image download time in Cloud and FlexConnect deployments where the AP and controller are separated by a WAN or Internet link, and
- is supported only on OEAP profiles.

CAPWAP communication and window enhancement

The wireless controller and the access point (AP) communicate with each other using CAPWAP. The CAPWAP has two channels, namely control and data. The control channel is used to send configuration messages, download images and client keys, or the context to the AP. The control channel has a single window in the current implementation. A single window means that every message that is sent from the controller has to be acknowledged by the AP. The next control packet is not transmitted till the earlier one is acknowledged by the AP.

The AP Image Download Time Enhancement feature adds support to multiple sliding windows for control packets going from controller to AP. The sliding window can be set to N (static) instead of a single window. The request queue size is decided based on the maximum window size the AP supports.

The following table shows the recommended window size for different network conditions:

Table 22: Recommended window size

Link Bandwidth[1]	Less than 200 ms RTT	Greater than 200 ms RTT
More than 20 Mbps	10	15
Between 5 and 20 Mbps	10	15
Between 1 and 5 Mbps	5	10
Less than 1 Mbps	3	5

Note

- The window size can be changed only during the AP join process.
- All image upgrades should be in the **install** mode for faster upgrade. Image upgrade should be done from the **one-shot** command to include OEAP predownload.
- Configure the window size only for AP profiles that are exclusively used for Teleworker or Office Extend Access Points (OEAP).
- An AP reload is not required after disabling this feature.
- This feature is supported only on the OEAP profiles.
- GUI does not support AP predownload. Therefore, the AP downloads after disjoining the controller during CAPWAP join phase. This causes a long disruption in the network as the Image download for AP can take upto one hour.

Important

If you downgrade the software to Cisco IOS XE Gibraltar 16.12.4 or earlier from Cisco IOS XE Amsterdam 17.3.1, you should reset the CAPWAP multi window to a single window prior to the downgrade. Failure to do so necessitates a manual AP recovery.

High-level workflow for AP Image Download Time Enhancement:

1. Select an existing AP join profile or create a new one.
2. Set the CAPWAP window size.
3. Associate the AP join profile to an existing site tag or new one.
4. Apply the site tag to the AP using: Static, Filter, Location, AP, or Default mapping method.

Configure AP Image Download Time Enhancement (GUI)

Configure AP Image Download Time Enhancement using GUI to optimize access point image download performance.

[1] The window size recommendation provided in the table is for packet loss of less than one percent (< 1%). If the network supporting the CAPWAP link has packet loss of more than one percent (> 1%), use a smaller value for window size. For good links with round-trip time (RTT) of about 100ms and packet drops of less than half a percent (< 0.5%), use a window size of up to 20 for better performance.

AP Image Download Time Enhancement optimizes the download performance of access point images by configuring CAPWAP window size settings to improve data transfer efficiency.

Use this procedure when you need to optimize access point image download performance through CAPWAP configuration settings. This enhancement is particularly useful in environments with high-latency network connections or when managing large numbers of access points.

Follow these steps to configure AP Image Download Time Enhancement using the GUI:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join** > **CAPWAP > Advanced**.
2. In the **CAPWAP Window Size** field, enter the unit of measurement of the window.
3. Click **Save & Apply to Device**.

The AP Image Download Time Enhancement configuration is applied to the device. Access points will use the optimized CAPWAP window size settings for improved image download performance.

Configure AP Image Download Time Enhancement (CLI)

Configure AP Image Download Time Enhancement using commands.

Enable AP Image Download Time Enhancement to optimize the download process for access points.

AP Image Download Time Enhancement improves the efficiency of firmware downloads to access points by configuring the CAPWAP control packet transmit queue size. This configuration is particularly beneficial for teleworker or OEAP deployments.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

   Example

   ```
   Device(config)# ap profile capwap_multiwindow
   ```

3. Configure the AP CAPWAP control packet transmit queue size.

   Example

   ```
   Device(config-ap-profile)# capwap window size window-size
   ```

Example

```
Device(config-ap-profile)# capwap window size 20
```

Note

Configure the window size only for AP profiles that are exclusively used for teleworker or OEAP.

Be aware that any change in window size may impact other APs.

For standard AP deployments, retain the default CAPWAP window size of `1`. Configure a higher value only for AP profiles used exclusively for Teleworker or OfficeExtend APs. If APs repeatedly disconnect and rejoin the controller or experience CAPWAP keepalive timeouts, reset the value to `1` using `no capwap window size` or `capwap window size 1`.

4. Return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

The AP Image Download Time Enhancement is now configured with the specified CAPWAP window size, optimizing firmware download performance for the designated AP profile.

Verify AP image download time enhancement configuration

Provides commands to verify AP Image Download Time Enhancement Configuration.

Verify AP Image Download Time Enhancement Configuration using commands to view CAPWAP window size, status, and modes.

To view the CAPWAP window size present in an AP profile, use this command:

```
Device# show ap profile name default-ap-profile detailed | in wind

Capwap window size : 10
```

To view the CAPWAP status and modes, use this command:

```
Device# show capwap client rcb

OperationState                      : UP
Name                                : AP4001.7A39.2D5A
MwarHwVer                           : 0.0.0.0
Location                            : default location
ApMode                              : Remote Bridge
ApSubMode                           : Not Configured
CAPWAP Path MTU                     : 1485
Software Initiated Reload Reason    : Reload command
CAPWAP Sliding Window
Active Window Size                  : 10
Last Request Send To Application    : 184
```

```
Expected Seq Num                    : 185
Received Seq Num                    : 184
Request Packet Count                : 42424
Out Of Range Packets Count          : 0
Window Moved  Packets Count         : 0
In Range Packets Count              : 960
Expected Packets Count              : 41464
```

To view the AP configuration details, including the CAPWAP window size, use this command:

```
Device# show ap config general | in Wind

Capwap Active Window Size                         : 5
Capwap Active Window Size                         : 10
Capwap Active Window Size                         : 1
```

18 N+1 Hitless Rolling AP Upgrade

Topics:

- N+1 hitless rolling AP upgrade and version skew
- Site-based rolling AP upgrade in N+1 network
- Client steering enhancements

N+1 hitless rolling AP upgrade and version skew

N+1 hitless rolling AP upgrade and version skew are network upgrade strategies that enable wireless network upgrades with minimal or no downtime.

N+1 hitless rolling AP upgrade and version skew are network upgrade strategies that

- enable wireless network upgrades with minimal or no downtime
- allow software mismatches between wireless controllers and access points during upgrades, and
- support staged AP upgrades while maintaining service continuity.

Version skew: A compatibility feature that allows a controller to operate with APs running a different software version.

N+1 Hitless Rolling AP Upgrade: A controller-assisted method that migrates APs to a temporary controller during upgrade, avoiding service disruption.

Understanding N+1 Hitless Rolling AP Upgrade and Version Skew

Traditionally, all APs and the controller needed to be on the same software version to function properly, causing network downtime during upgrades. Version skew removes this limitation by allowing staged upgrades. Combined with the N+1 hitless rolling AP upgrade process, this strategy ensures continuous service by migrating APs to a temporary controller, upgrading the original controller, and then migrating APs back.

This method is especially beneficial in large-scale deployments where network availability is critical.

The following table contrasts the features of a traditional upgrade withvVersion skew + N+1 Upgrade:

Table 23: Comparison of Traditional Upgrade vs. Version Skew + N+1 Upgrade

Feature	Traditional Upgrade	Version Skew + N+1 Upgrade
Requires same version on all devices	Yes	No
Causes downtime	Yes	No
Supports staged AP upgrades	No	Yes
Uses secondary controller	No	Yes (WLC2 as mobility member)
Needs image pre-download	Not applicable	Yes, for ap image upgrade command

Examples of N+1 Hitless Rolling AP Upgrade

- A network admin can upgrade the controller (WLC1) while APs continue to operate from a mobility member (WLC2).
- Using the **`ap image move`** command after predowloading images avoids downtime even without simultaneous AP upgrades.

Counter-examples for N+1 Hitless Rolling AP Upgrade

- Upgrading all APs simultaneously without version skew or N+1 support would cause network downtime.
- Using the **`ap image upgrade`** command without pre-downloading the image will fail.

How N+1 hitless rolling AP upgrades work

This DITA XML content outlines the process for an N+1 hitless rolling AP upgrade.

This process involves upgrading controllers and managing access points using specific commands.

Summary

The N+1 hitless rolling AP upgrade process involves several critical steps: establishing mobility tunnels, upgrading software, moving APs, and activating new software images.

This process ensures a seamless upgrade of APs with minimal service disruption.

Workflow

Workflow for the N+1 hitless rolling AP upgrade feature

1. Establish a mobility tunnel from the controller (WLC1) to a mobility member (WLC2).
2. Upgrade the controller software (WLC1) using the **install add file bootflash:***new_version.bin* command.
3. You can also choose to upgrade the AP image.. For more information, see Predownloading an Image to an Access Point chapter.
4. Use the **ap image upgrade destination** *controller-name controller-ip report-name* privileged EXEC command to upgrade and move all the APs from WLC1 (source) to WLC2 (destination).
5. Activate the new image in WLC1 using the **install activate** command.
6. Commit the changes using the **install commit** command.
7. Move the APs back to WLC1 from WLC2 using the **ap image move destination** *controller-name controller-ip report-name* command.

> **Note**
>
> The **ap image upgrade destination** command does not work without an image pre-download. If you do not perform an image pre-download, use the **ap image move** command to move the APs. When APs download the image and join the destination controller, you must set the iteration time as high. Also, you can customize the iteration time by configuring the **ap upgrade staggered iteration timeout** command.

Result

The process upgrades access points effectively without disrupting service. It maintains optimal network functionality during transition stages.

Configure hitless upgrade

Configure hitless upgrade using commands.

The purpose of this task is to perform a hitless upgrade using a zero downtime network upgrade process in an N+1 deployment. This process ensures that all necessary components are pre-checked for compliance, and the upgrade is carried out smoothly with minimal disruption.

Before you begin

- Provide the hostname and wireless management IP of the destination controller in the privileged EXEC command.
- Predownload the image on APs running on the destination controller.

Procedure

1. Move the APs to the specified destination controller with the Swap and Reset command.

   Example

   ```
   Device# ap image upgrade destination wlc2 10.7.8.9
   ```

   After this, the parent controller activates the new image and reloads with the new image. Establish the mobility tunnel, and then return APs to the parent controller without a swap and reset.

   > **Note**
   >
   > Ensure that you establish a mobility tunnel from controller (WLC1) to a mobility member (WLC2) before image upgrade.

2. Optional: Moves APs to the specified destination controller with a swap and reset command.

   Example

   ```
   Device# ap image upgrade destination wlc2 10.7.8.9
   ```

   > **Note**
   >
   > Steps 2 to 4 should only be performed if Step 1 is not being executed.

3. Move the APs back to the parent controller.

   Example

   ```
   Device# ap image move destination wlc1 10.7.8.6
   ```

4. Optional: Move APs to the specified destination controller with a swap and reset command.

   Example

   ```
   Device# ap image upgrade destination wlc2 10.7.8.9 fallback
   ```

   After that, APs move back to the parent controller (without a swap and reset) once the new image is manually installed and the parent controller is reloaded.

5. Optional: Move APs to the specified destination controller using the Swap and Reset command.

   Example

   ```
   Device# ap image upgrade destination wlc2 10.7.8.9 reset
   ```

After this, the parent controller activates the new image and reloads with the new image.

The result of this task is a successful upgrade of the network without any downtime, ensuring the APs are returned to the parent controller seamlessly after the upgrade is complete. The network continues to function optimally with the new image installed.

Verify hitless upgrade

Verify Hitless Upgrade using commands.

Use these commands to verify hitless upgrade.

These are the commands to verify hitless upgrade.

- To view all the upgrade report names, use this command:

```
Device# show ap upgrade summary

Report Name      Start time

Site-based rolling AP upgrade in N+1 network

Introduces site-based rolling AP upgrade in N+1 networks, detailing prerequisites, restrictions, use cases, upgrade workflows, CLI configuration, hitless software upgrades, and verification procedures for optimal AP migration and network reliability.

The site-based rolling AP upgrade in an N+1 network is a feature that

- effectively achieves a zero-downtime network upgrade in an N+1 network
- allows you to perform a software upgrade of a site or all the sites managed by the controller, and
- upgrades the software of the APs belonging to a site and monitors the network to see whether it is functioning as intended before adding more sites to the site filter.

Feature history for site-based rolling AP upgrade in N+1 networks

This table provides release and related information for the features explained in this module.

These features are available in all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 24: Feature history

Release	Feature	Feature Information
Cisco IOS XE 17.9.1	Site-Based Rolling AP Upgrade in N+1 Network	This feature helps to achieve a zero downtime network upgrade in N+1 networks.

> **Note**
>
> If the upgrade fails to meet the objectives, all the sites in the site filter can be removed using the **ap image site-filter file any-image remove-all** command.

The **ap image site-filter** command is modified to include the **any-image** keyword that is a substitute for the image file name to support the N+1 AP move site filter.

Prerequisites for site-based rolling AP upgrade in N+1 networks

Prerequisites for site-based rolling AP upgrade in N+1 networks.

Ensure these conditions are met for site-based rolling AP upgrade in N+1 networks

- The source and destination controllers should be in the same mobility group (preferably running the latest image) but with different AP image versions.
- Image of the destination controller should be available on the source controller.
- Both the source and destination controllers should be in INSTALL mode.
- If you reboot the source or destination controller during the N+1 upgrade, you must re-execute the procedure.

Restrictions for site-based rolling AP upgrade in N+1 networks

Restrictions for site-based rolling AP upgrade in N+1 networks

- Site filter operations are supported only for N+1 upgrade and N+1 move; **fallback** and **reset** options of the **ap image upgrade destination** command are not supported.
- You can move APs between controllers that have the same software.
- The keywords **any** and **remove-all** of the **ap image site-filter** command work only for the N+1 procedures: AP upgrade or move. It will not work for other site filter operations such as AP Model Service Pack (APSP) or AP Device Package (APDP).

Best practices for N+1 redundancy deployments

Use Cases for N+1 redundancy deployments.

Use spare controllers in N+1 redundancy deployments to allow APs to fail over when the primary controller becomes non-operational. This approach ensures minimal network downtime, typically lasting 30 to 40 seconds, as APs discover and join the network in local mode.. Ensure all devices reboot and converge efficiently within the N+1 deployment framework to achieve effective zero-downtime during network upgrades.

Configure site-based N+1 upgrade (CLI)

Configure site-based N+1 upgrade using commands.

This document provides a reference on configuring site-based N+1 upgrades using CLI commands. The configuration involves several critical settings and actions which ensure seamless transitions and effective management of access points across controllers.

These are the key commands and configuration steps

- Configure Iteration settings for N+1 Upgrade on Primary Controller
- Configure Site Filters for Predownload and Move APs to Spare Controller
- Return APs (Per-Site) to Primary Controller using Site Filters

Configure iteration settings for N+1 upgrade on source controller (CLI)

N+1 upgrade and move to destination controller using commands.

This task involves executing a sequence of CLI commands to set iteration parameters for conducting an N+1 upgrade on the source controller.

Before you begin

- See the *Prerequisites for Site-based Rolling AP Upgrade in an N+1 Network* section
- Run all the commands only on the source controller
- To disable the 11v message, use **no ap upgrade staggered client-steering** command.

Procedure

1. Enter global configuration mode

Example

```
Device# configure terminal
```

2. Optional: Disable client steering

   Example

   ```
   Device# no ap upgrade staggered client-steering
   ```

3. Optional: Configure the minimum percentage of APs that must join the destination controller to signal iteration completion.

   Example

   ```
   Device(config)# ap upgrade staggered iteration completion 50
   ```

4. Optional: Configure the action to be taken when APs are missing after an iteration

   Example

   ```
   Device(config)# ap upgrade staggered iteration error action stop
   ```

5. Optional: Configure the maximum time allowed per iteration during AP upgrade.

   Example

   ```
   Device(config)# ap upgrade staggered iteration timeout 18
   ```

   Valid values range from 9 to 60.

6. Return to privileged EXEC mode

   Example

   ```
   Device(config)# exit
   ```

The APs upgrade and move to the designated destination controller within the mobility group. Any configured site filters and settings will be applied, ensuring that the APs operate under optimal conditions as defined during the configuration process.

Configure site filters for predownload and move APs to destination controller (CLI)

N+1 upgrade and move to destination controller using commands.

The purpose of this task is to guide users through configuring site filters and performing a controlled predownload of AP images, ensuring a seamless upgrade and transition to the designated destination controller within an N+1 network environment.

Before you begin

See the *Prerequisites for Site-based Rolling AP Upgrade in an N+1 Network* section.

- Run all the commands only on the source controller.

Procedure

1. Add a site tag to a site filter

   Example

   ```
   Device# ap image site-filter any-image add site1
   ```

   You can repeat this step to set up a multisite filter.

2. Move the APs to a different controller in the mobility group.

   Example

   ```
   Device# ap image move destination controller2 10.9.34.4
   ```

   Note

   It is preferable to move the APs to a different controller running the same image.

   Wait for the upgrade to complete.

   If upgrade is not completed successfully, you can use the **ap image upgrade destination** or **ap image move destination** commands to restart the upgrade process.

3. Add additional site tag to a site filter

   Example

   ```
   Device# ap image site-filter file any-image add site2
   ```

4. Predownloads the image and upgrades the APs based on the site filter.

   Example

   ```
   Device# ap image site-filter file any-image apply
   ```

   Note

   Wait for the upgrade to complete.

5. Optional: Clear the site filter table and predownloads the image and does a rolling AP upgrade to all the sites.

   Example

   ```
   Device# ap image site-filter file any-image clear
   ```

6. Optional: Remove all the site filters

Example

```
Device# ap image site-filter file any-image remove-all
```

Upon completion of this task, APs will be upgraded and transitioned to the selected destination controller, operating under optimized conditions with all site filter configurations applied. This process ensures robust performance and continuity within the mobility group.

Return APs (per-site) to source controller using site filters

N+1 move to destination controller using commands.

This task will help to manage and transition APs in an N+1 network environment by adding site tags, moving APs to controllers, and upgrading the APs based on defined site filters.

Run all the commands only on the source controller.

Before you begin

See the *Prerequisites for Site-based Rolling AP Upgrade in an N+1 Network* section.

Procedure

---

1. Add a site tag to a site filter.

   Example

   ```
   Device# ap image site-filter any-image add site1
   ```

2. Move the APs back to the parent controller.

   Example

   ```
   Device# ap image move destination controller2 10.9.34.2
   ```

   Note

   Wait for the upgrade to complete.

3. Add an additional site tag to a site filter.

   Example

   ```
   Device# ap image site-filter any-image add site2
   ```

4. Upgrade the APs based on the site filter.

   Example

   ```
   Device# ap image site-filter any-image apply
   ```

> **Note**
>
> Wait for the upgrade to complete.
>
> If upgrade is not completed successfully, use the **ap image upgrade destination** or **ap image move destination** command to restart the upgrade process.

5. Optional: Clear the site filter table and predownloads the image, and performs a rolling AP upgrade to all sites where it is not active.

Example

```
Device# ap image site-filter any-image clear
```

Completing this task successfully ensures efficient management of APs within the N+1 network environment. All APs are upgraded and operate with the correct site tags and configurations.

Upgrade workflow for site-based N+1 upgrade

Upgrade workflow for site-based N+1 upgrade

The site-based N+1 upgrade process enhances network reliability by utilizing spare controllers, ensuring seamless software updates without disrupting ongoing service and supporting continuous uptime in enterprise environments.

Summary

Hitless software upgrade uses the concept of N+1 high availability using a spare controller to upgrade the CAPWAP infrastructure comprising controllers and APs. Depending on your choice, the APs are upgraded in a staggered fashion either per site or on all sites using the rolling AP upgrade feature, thereby avoiding network disruption. This ensures that the clients are serviced by neighboring APs while one or selected APs undergo the upgrade process.

Workflow

1. Initiate upgrade on the source controller. You can choose to upgrade all sites or per site based on your preference.
2. Move the APs to the destination controller. APs are upgraded in a staggered fashion using the rolling AP upgrade algorithm.
3. After all the APs move to the destination controller through multiple iterations, activate the target image on the source controller.
4. The source controller reloads for the new image to take effect.
5. (Optional) Move the APs back to the source controller using the cli commands.

Result

The process ensures N+1 availability with uninterrupted service to clients while successfully updating AP infrastructure.

Configure site-based N+1 upgrade (GUI)

Hitless software upgrade using GUI.

This task provides instructions to configure a site-based N+1 upgrade using the GUI on a controller. This ensures that the upgrade process is seamless and minimizes downtime for APs and controllers.

Before you begin

- The controller should be in **INSTALL** mode.
- The controller should be paired with another controller and both should be part of the same mobility group.

  The spare controller should be upgraded with the target image.

Procedure

1. Choose **Administration > Software Management** .
2. From the **Transport Type** drop-down list, choose an option.

   Note

   In the **File Path** field, enter the complete path from where you want to download the software image file, including the name of the file.

   - If you choose **My Desktop** as the transport type, click **Select File** to navigate to the file from the **Source File Path** field.
   - If you choose **SFTP** as the transport type, enter the source IP address, SFTP username, SFTP password, file path, and select the destination.
   - If you choose **FTP** as the transport type, enter the source IP address, FTP username, FTP password, file path, and select the destination.
   - If you choose **TFTP** as the transport type, enter the source IP address, file path, and select the destination.

     Note

     In controllers, the IP TFTP source is mapped to the service port by default.

   - If you choose **Device** as the transport type, choose the file system and file path.
3. Check the **Enable Hitless Upgrade** check box to allow the APs and the controller to be upgraded.
4. From the **Site Filter** drop-down list, choose **All Sites** or one or more **Custom Sites**.

   In case you choose to upgrade for **All Sites**, you can optionally enable **Fallback after Upgrade** so that the APs move back to the parent controller after the new image has been activated and the parent controller has reloaded.

   In case you choose a **Custom Site**, select the site from the **Site Tags** drop-down list. In this case, the APs do not move back to the parent controller automatically and you will have to manually move them using CLIs.
5. In the **Controller IP Address (IPv4/IPv6)** field, enter the source controller's IPv4/IPv6 address.
6. In the **Controller Name** field, enter the source controller's name.
7. In the **AP Upgrade Configuration** section, use the **AP Upgrade per Iteration** drop-down list to select the percentage of APs to be upgraded per iteration. This configures the minimum percentage of APs that must join the destination controller to signal completion of iteration.
8. Check the **Client Steering** check box to move clients attached to APs undergoing an upgrade to other APs. If the clients still persist on the candidate APs, they are disconnected and the APs will reload with the new image.
9. In the **Accounting Percentage** field, choose the percentage of APs that should join the destination controller after each iteration (of the staggered AP upgrade) to consider the iteration as successful. The default value is 90%.

10. Tap to select the type of **Accounting Action** to configure for the APs. If you enable **Terminate**, the upgrade is terminated if the configured percentage of APs does not join the mobility peer, and a notification is sent via Syslog message. If you choose **Ignore**, the upgrade continues irrespective of whether the configured percentage of APs are joining the controller or not.
11. In the **Iteration Expiry** field, select the number of minutes from the drop-down list to configure the expiry time for each iteration.
12. Click **Download & Install**.
13. Click **Save Configuration & Activate**.
14. Click **Commit** to make the activation changes persistent across reloads.

Upon successful completion of the upgrade process, the controllers and APs should operate with the new software image with minimal disruption to network operations. The reliability and performance of the network are maintained during the transition.

Verify site-based rolling AP upgrade in a N+1 network

Verify site-based rolling AP upgrade in a N+1 network using commands.

The commands ensure the successful implementation and seamless operation of site-based rolling AP upgrades within an N+1 network. By utilizing these commands, you will be able to monitor the progress, evaluate the status, validate updates, and troubleshoot potential issues related to AP upgrades.

Use these AP commands to check the progress of the upgrade and debugging

- **show ap summary**
- **show ap tag summary**
- **show ap status**
- **show wireless mobility summary**
- **show ap image**
- **show ap upgrade**
- **show ap upgrade site**
- **show ap upgrade site summary**
- **show ap upgrade name** *report-name*
- **show wireless mobility ap-list**

To view the summary of all the connected APs, use this command

```
Device# show ap summary

Client steering enhancements

Introduces client steering enhancements that optimize client management during staggered AP upgrades, minimize unnecessary disconnections, and provide greater control over steering behavior for both new and existing clients.

Client steering enhancements are configuration options that

- improve how clients are managed during staggered access point (AP) upgrades,
- help maintain client connectivity by avoiding unnecessary disconnections, and
- offer more control over steering behavior for both new and existing clients.

Client deauthentication

This topic aims to provide a comprehensive understanding of client deauthentication during staggered upgrades of access points in a wireless network.

When access points (APs) of a wireless network are upgraded in a staggered manner, the clients connected to those APs are moved to other APs. During this period, clients that are unaware of an ongoing upgrade may try to reassociate with the same AP. Similarly, new clients may also try to join the AP. To avoid this scenario, Cisco IOS XE Dublin 17.11.1 introduces the option to not deauthenticate clients connected to the APs that are selected for the upgrade. Using the `no ap upgrade staggered client-deauth` command, you can stop deauthenticating clients before the AP performs an upgrade.

Client deauthentication affects both the 802.11v clients and non-802.11v clients. When client steering is enabled, 802.11v clients receive Basic Set Service (BSS) transition frames that guide them to roam. If client steering is disabled and deauthentication is enabled, even 802.11v clients receive deauthentication messages, which may result in dropped connections.

Best practice for preserving client connectivity during upgrade

Best practice for preserving client connectivity during upgrade

Ensure that client deauthentication is disabled on APs selected for upgrade. This minimizes disruption and maintains better client experience, especially in high-availability wireless environments.

Deauthenticate clients

Deauthenticate clients associated with the AP before an image upgrade.

This task allows you to manage client connections by deauthenticating clients associated with the access point (AP) before performing an image upgrade.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Stop deauthentication of the clients associated with the AP before the AP starts to upgrade.

   Example

   ```
   Device(config)# no ap upgrade staggered client-deauth
   ```

3. Return to privileged EXEC mode

Example

```
Device(config)# end
```

Successful execution of this task ensures that clients are not unexpectedly disconnected during an AP image upgrade.

19 NBAR Dynamic Protocol Pack Upgrade

Topics:

- Network-based application recognition protocol pack upgrade

This chapter explains how to update and manage NBAR protocol packs to extend application recognition without rebooting, describes deployment and limitations (encryption, QUIC, DoH), and provides CLI upgrade steps.

Network-based application recognition protocol pack upgrade

Introduces NBAR protocol packs, detailing their role in updating application protocol support, key components, and upgrade features that enable seamless version changes without device reloads or service disruption.

A protocol pack is a software module for Network-Based Application Recognition (NBAR) that:

- adds or updates support for application protocols without replacing the Cisco software on the device
- comes as a built-in component for each Cisco software release, and
- allows easy version upgrades and reversion without service disruption or device reload.

Protocol packs contain:

- application protocols that are compiled and officially supported by NBAR, and
- information on the signatures and attributes of the application.

Protocol packs offer these features:

- They can be loaded easily and quickly.
- You can upgrade to a later version protocol pack or revert to an earlier version.
- Device reload is not required.
- No service disruption occurs.

Application visibility controls with DPI

Deep packet inspection for application visibility and control.

A deep packet inspection (DPI) is a method that

- inspects data packets for detailed application visibility,
- allows for custom traffic definitions, and
- supports distributed analysis for wireless networks.

Wireless products use the Application Visibility and Control feature through a distributed system where Network-Based Application Recognition (NBAR) runs on controllers or access points, performs deep packet inspection, and reports via NetFlow messages.

Deployment mode

Although NBAR is supported in all the modes, protocol pack upgrade and custom applications are only supported in local mode (central switching) and in FlexConnect mode (central switching).

Important

When you upgrade the AVC protocol pack:

- Copy it to both route processors (RPs), active and standby.
- Otherwise, the standby protocol pack upgrade will fail and cause a synchronization failure crash.

NBAR limitations

Limitations of NBAR.

NBAR struggles to classify traffic when SaaS applications use certain technologies, impacting traffic classification.

- End-to-end encryption.
- Quick UDP Internet Connections (QUIC) protocol.
- DNS over HTTPS (DoH) protocol.

> **Note**
>
> In such a case, the encrypted traffic, including DoH and QUIC without SNI, limits the ability of NBAR to send the correct Protocol ID, causing issues with traffic classification.

Protocol pack upgrades and custom application configuration

Overview of protocol pack upgrades and custom application configuration.

Optimize network management by implementing protocol pack upgrades and customizing application recognition rules to meet specific traffic analysis needs.

Protocol pack upgrade

- Protocol pack upgrades allow the update of the NBAR engine to recognize new types of protocols or traffic without requiring an update to the entire switch or appliance image.
- This process eliminates the need to restart the entire system after the upgrade.
- NBAR protocol packs can be downloaded from Cisco Software Center.

Custom applications

- Configure the NBAR engine to recognize traffic based on custom rules, such as destination IP, hostname, or URL.
- The web UI and NetFlow collector display custom application names, allowing for easier identification and management.

Upgrade the NBAR2 protocol pack (CLI)

Upgrade the NBAR2 protocol pack using commands.

The purpose of this task is to upgrade the NBAR2 protocol pack on your network device. By upgrading, you enhance the application's recognition capabilities, allowing for more effective network management and traffic classification.

Upgrade the NBAR2 protocol pack by completing these steps

Before you begin

Download the protocol pack from the Software Download page and copy it into the bootflash, `#copy tftp://10.10.10.1/pp-adv-c9800-1712.1-49-70.0.0.pack bootflash:`

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Load the protocol pack.

   Example

   ```
   Device(config)# ip nbar protocol-pack bootflash:mypp.pack
   ```

Upgrading the protocol pack successfully ensures that your device can recognize a wider range of applications, enhancing traffic monitoring and classification.

Verify the NBAR2 protocol pack

This section provides details on how to verify the NBAR2 protocol pack.

To verify NBAR protocol pack version, use this command:

```
Device# show ip nbar protocol-pack active
```

20 Wireless Sub-Package for Switch

Topics:

- Wireless sub-packages

Wireless sub-packages

Introduces wireless sub-package concepts and guides users through installing, removing, and upgrading wireless packages. Details procedures for sub-package installation, single-step and multi-step methods, stack deployment, upgrading packages, deactivation, and enabling or disabling auto-upgrade functionality.

A wireless sub-package is a component within a network architecture that

- integrates seamlessly with existing network designs such as multitier, Routed Access, and Virtual Switching System (VSS)
- uses Locator/ID Separation Protocol (LISP) for control planes and Virtual Extensible LAN (VXLAN) for overlay data planes
- maintains wireless control planes through Control and Provisioning of Wireless Access Points (CAPWAP) tunnels connecting AP with controllers.

Benefits of the controller

- Centralized control simplifies configuration, troubleshooting, and upgrades.
- The controller provides high throughput and distributed forwarding for enhanced network services.
- The controller facilitates scalable services such as Application Visibility and Control (AVC) without splitting control planes into MC and MA.

Install and activate sub-packages

1. Identify the network nodes that need enhanced wireless capabilities.
2. Deploy the sub-package on top of the base image on the relevant switches.
3. Reload the system to activate the newly installed sub-package.

> **Note**
>
> The sub-package is an optional binary that contains the entire Cisco Catalyst 9800 Series Wireless Controller software.

Deployment considerations

- Provision and deploy Cisco Catalyst 9800 Wireless Controller software on Cisco Catalyst 9300 switches using Cisco Catalyst Center. Standalone controller configuration is not supported. For additional information, see Cisco Catalyst 9300 Series Switches Hardware Installation Guide.
- SNMP Compatibility: SNMP is not supported on Catalyst 9800 Embedded Wireless Controllers.
- The sub-package contains the complete Cisco Catalyst 9800 software suite, optimally deployed using Cisco Catalyst Center. For more details, see the Cisco Catalyst 9300 Series Switches Hardware Installation Guide.
- Verify that network configurations and conditions meet operational requirements to achieve optimal performance.

Install wireless packages

How to install wireless package

Summary

Installing the wireless package is essential for enabling wireless capabilities on a switch. This process allows the switch to handle wireless access points and manage network traffic efficiently, thereby expanding its functionality within a network environment.

Workflow

The process involves these stages:

1. Install the base image: load the base image (excluding wireless) onto the switch to prepare it for further installations.
2. Install the wireless package: add the wireless package to the switch to enable wireless features.
3. Upgrade the AP image: ensure that the access point image is updated to the latest version for compatibility and performance.
4. Reload the switch: restart the switch to apply the new settings and updates.
5. Enable and configure wireless: use the **configuration command** to activate wireless on the switch and configure the necessary wireless features.

Result

The switch has wireless capabilities enabled, allowing it to manage wireless connections and integrate seamlessly into a wireless network architecture.

Remove wireless package

How to remove wireless package.

Summary

Removing a wireless package involves uninstalling it, reloading the switch, and clearing configurations.

Workflow

Perform these steps to remove wireless package:

1. Uninstall: Remove the wireless package from the switch.
2. Reload: Reboot the switch to refresh system settings.
3. Clear Configuration: Run the **write** command to delete wireless settings from startup configuration.

Result

The switch will no longer contain any wireless packages or settings.

Upgrading wireless packages

Summary

This process outlines how to upgrade the wireless software on a switch, ensuring the system runs the latest version.

Workflow

Perform these steps to upgrade wireless packages

1. Install the base image: Start by setting up the switch with the base software version.
2. Install the updated wireless package: Load the new wireless version onto the switch.
3. Reload: Restart the switch to apply changes.
4. Commit: Finalize the installation to activate the updated package.

Result

The switch successfully runs the upgraded wireless software, improving its capabilities and resolving any prior issues.

Boot in install mode

Boot in Install Mode using commands.

Switch the boot mode from bundle-mode to install-mode using commands.

Use this procedure to boot the switch in install-mode

Before you begin

The sub-package does not work in bundle-mode. Use the **show version** command to verify the boot mode.

Procedure

1. Move the switch from bundle-mode to install-mode.

```
install add file image.bin location activate commit
```

   Note that *image.bin* is the base image.

2. Click **yes** to all the prompts.
3. Reload the switch.

```
Device# reboot
```

   Boot from *flash:packages.conf*. After the reload, the switch will be in install-mode.

> **Note**
>
> For image upgrade or downgrade in Install mode, the **Install add file** command with flash: *<file_name>* command is not supported. Instead of that bootflash: *<filename>* command needs to be used.

```
Install add file bootflash:file_name  activate commit
```

After completing this task, the switch will be in install-mode.

What to do next

Verify the boot mode using the **show version** command.

Install sub-package in a single step (GUI)

Install sub-package in a single step using GUI.

The purpose of this task is to install a sub-package using the graphical user interface in a single step.

Procedure

1. Choose **Administration** > **Software Management** > **Software Upgrade**.
2. Choose the upgrade mode from the **Upgrade Mode** drop-down list, the transport type from the **Transport Type** drop-down list and enter the **Server IP Address (IPv4/IPv6)**, the **File System** and choose the location from the **Source File Path** drop-down list.
3. Click **Download & Install**.

The sub-package is successfully downloaded and installed, ensuring the software is updated with the latest version.

Install sub-package in a single step

Install sub-package in a single step using commands.

The purpose of this task is to efficiently install a sub-package onto the switch in a single step, streamlining the update or installation process.

Before you begin

- Ensure that the switch is in install mode.
- Ensure that you boot only from *flash:packages.conf*.

Use this procedure to install sub-package in a single step

Procedure

1. **install add file** *flash:<controller>.bin* **activate commit**

   Installs the Cisco Catalyst 9800 Wireless Controller for Switch sub-package.

   > **Note**
   >
   > The sub-package (flash:<controller>.bin) is available on www.cisco.com. You can also install the sub-package directly from TFTP server.

2. Click **yes** to all the prompts.

Upon completion, the sub-package will be successfully installed and activated on the switch, ready for its verification and use.

What to do next

Use the **show install summary** command to verify the installed image or package.

Install multi-step sub-package

Install multi-step sub-package using commands.

This task provides steps to install a multi-step sub-package on a switch.

Before you begin

Ensure that the switch is in install-mode and boot only from flash:packages.conf.

Procedure

1. Add sub-package to the flash and expand.

   install add file *flash:<controller>.bin*

2. Install the sub-package.

   install activate file *flash:<controller>.bin*

3. Complete the installation by writing the files.

   install commit

The sub-package installation is completed successfully, and the system is ready for operation.

What to do next

Use the **show install summary** command to verify the installed image or package.

Install the package on a stack

Install the package on a network stack using a structured method.

Use a structured method to install the package on a network stack.

Before you begin

- Ensure you have the correct permissions.
- Determine if auto-upgrade is enabled or disabled for any new members.

Procedure

1. Verify the current version running on the stack.
2. Choose the installation method:
   - Use Single-step Package Installation if applicable.
   - Refer to the multi-step installation guide as required.
3. If a new member joins, there are two possible scenarios.

if auto-upgrade is enabled	confirm the software automatically installs.
if auto-upgrade is disabled	run the **install autoupgrade** command in EXEC mode manually.

The package is installed, and new stack members are aligned with the current software version, maintaining consistency across the system.

Upgrade to new version of wireless package

Upgrade to new version of wireless package using commands.

Upgrade the wireless package to the latest version by executing specific commands.

Use this procedure to upgrade to the new version of wireless package

Procedure

1. Add the base image (without wireless) to the flash and expand it.

   install add file *flash:<base-image>.bin*

2. Add the sub-package to the flash and expand it.

   install add file *flash:<controller-sub-package>.bin*

3. The system executes the installation of the base image and sub-package, which causes a reload.

   install activate

   You can also rollback to the previous state after the reload.

4. Complete the installation by writing the files.

   install commit

The latest wireless package version runs on your system. You can rollback if necessary.

Deactivate wireless package

Deactivate the wireless package using commands.

You can deactivate the wireless package on a device to ensure it operates without wireless functions through this task.

Follow this procedure to deactivate the wireless sub-package:

Procedure

1. Remove the package and force the switch to reboot

   Example

   ```
   Device# install deactivate file flash:<controller>.bin
   ```

   Removes the package and forces the switch to reboot.

2. Commit the switch without wireless package

   Example

   ```
   Device# install commit
   ```

Commits the switch without wireless package.

The device reboots and ensures that only non-wireless functions are available by operating without the wireless package.

Enable or disable auto-upgrade

Enable or disable auto-upgrade using commands.

The purpose of this task is to manage the auto-upgrade capabilities of the software on the device, allowing you to either enable or disable automatic upgrades according to operational needs.

Use this procedure to enable or disable auto-upgrade

Procedure

---

1. Enable software auto-upgrade

   Example

   ```
   Device(config)# software auto-upgrade enable
   ```

   Enables software auto-upgrade.

2. Disable software auto-upgrade

   Example

   ```
   Device(config)# no software auto-upgrade enable
   ```

   Disables software auto-upgrade.

The device either automatically updates its software when new firmware is available or remains on its current software version without automatic upgrades, depending on the command executed.

Part III

Lightweight Access Points

Topics:

- Global Use Access Points
- Countries and Regulations
- Security
- AP Joining
- AP Crash File Upload

21 Global Use Access Points

Topics:

- Global use access points
- AP mode of options
- Cisco regulatory domain
- E-Label display

About Global Use APs.

Global use access points

Introduces the concept of global use APs and highlights best practices, detailing their benefits and essential considerations for deployment and use in various regulatory environments.

Global use access points (APs) are network devices that

- operates in both Meraki cloud native networks and Catalyst on-premise controller-based networks
- uses a single product ID (PID) for simplified logistics, and
- decouple PID or SKU from regulatory domains and boot modes.

The transition to a unified PID model reduces SKUs from around 16 product ID (PIDs) to nine by introducing Rest of World (RoW) APs, which support country-specific configurations. In contrast, non-RoW APs remain restricted due to strict regional compliance policies.

Regulatory compliance and global use AP

The important aspects that the Global Use AP addresses for Catalyst and Meraki Cloud setups are the AP mode of operation and the adherence to Cisco Regulatory Domain requirements, ensuring compliance with regulatory standards on radio channel usage and power limits across different geographical bands.

Benefits of global use AP

Global use AP benefits.

Global use APs offer numerous advantages that enhance network management efficiency and flexibility. The benefits of global use APs are:

- One PID to order Cisco Catalyst or Meraki mode APs
- Seamless provisioning
- Easily transition from Catalyst mode to Meraki mode to meet network needs
- Reduce complexity with no reliance on country-specific SKUs

AP mode of options

Explains supported AP operating modes and workflows, covering Cloud ID, Day 0 onboarding, prioritized migration methods, fast offline migration steps, local status and offline migration details, and strategies to prevent false migration.

An AP mode option is a provisioning choice that

- allows the AP to operate in either Meraki Cloud mode or Catalyst controller mode
- can be set during the initial deployment or after deployment
- and enables the AP to join the appropriate management system.

Cloud IDs

A Cloud ID is an identifier that

- represents the Meraki Serial Number for a device
- appears on the device's physical label, packaging, QR code, and related materials, and

- is essential for the Meraki device claim workflow in networks using devices such as the Cisco Wireless 917x series AP.

Additional reference information

The Cloud ID enables the streamlined claiming and management of Meraki devices within cloud-managed workflows. From the Cisco Wireless 917x series AP onward, this identifier provides a consistent reference for inventory and setup operations.

- A network administrator uses the Cloud ID printed on the access point's label to claim the device in the Meraki dashboard.
- The QR code containing the Cloud ID simplifies device onboarding for IT staff.

A device serial number used in traditional on-premises workflows is not considered a Cloud ID unless it participates in the Meraki cloud claim process.

Onboarding process for Wi-Fi 7 APs

Describes the brief details of the Day 0 onboarding workflow.

This section describes how to connect Cisco Catalyst 917x Wi-Fi 7 APs (CW917x) to the Meraki Dashboard and the Cisco Catalyst 9800 Wireless LAN Controller.

Summary

This process involves connecting the APs to the Meraki Dashboard and migrating them to the Cisco Catalyst 9800 Wireless LAN Controller.

The key components involved in the process are

- Cisco Catalyst 917x Wi-Fi 7 APs (CW917x): The APs must be powered on and claimed on the Meraki dashboard.
- Meraki Dashboard: Cloud-based management platform for onboarding APs.
- Cisco Catalyst 9800 Wireless LAN Controller: Final migration destination for managing APs.

Workflow

These stages describe connecting the APs to the Meraki Dashboard and migrating to the Cisco Catalyst 9800 Wireless LAN Controller.

1. Stage 1: Connect to Meraki Dashboard
   - Power on APs.
   - Claim APs using order number, Cloud ID, or MAC address. You can see the claimed APs on the Meraki dashboard as they start up.

   > **Note**
   >
   > Ensure there are no DHCP, DNS, or PnP configurations that can lead the CW917x AP to the controller.

2. Stage 2: Migrate the APs to the Cisco Catalyst 9800 Wireless LAN Controller
   - **Option 1:** Cloud-assisted migration If internet is available and the Meraki Dashboard account is configured, allow APs to join the dashboard and then migrate to the controller.
   - **Option 2:** Offline or fast offline migration If no internet is available:

- Offline migration uses DHCP or DNS without changes to the existing network.
- Fast offline migration uses new DHCP or DNS settings and skips cloud verification.

- If fast offline migration is not used, the AP will
  - search for the Meraki cloud for eight minutes, and
  - after eight minutes, check DHCP or DNS for the controller and migrate via CAPWAP discovery.

Result

APs successfully transition from initial setup in the Meraki Dashboard to established operational management under the controller, ready for enhanced performance and control.

Priority order for AP migration methods

To ensure efficient and reliable AP migration, use the following methods in priority order. Select the highest-priority method available for your deployment.

The migration methods are prioritized in this order

- Fast Offline Migration
  - DHCPv4
  - DNSv4
  - DHCPv6
  - DNSv6
- Local Status Page
  - You can manually migrate the APs through the Local Status window of the AP when Fast Offline Migration options are not available.
- Offline Migration
  - DHCPv4
  - DHCPv6
  - DNSv4
  - DNSv6
  - Broadcast or Multicast Discovery

Fast offline migration

Follow these steps to perform a fast offline migration for DHCPv4, DHCPv6, DNSv4, and DNSv6.

This task guides you through the process of executing a fast offline migration using DHCPv4, DHCPv6, DNSv4, and DNSv6 configurations to ensure network stability and performance.

This procedure is essential for network environments requiring quick migration of APs to a new controller mode, leveraging DHCP and DNS configurations.

Procedure

1. DHCPv4: The fast offline migration for DHCPv4 is Option 43.

   The syntax for the option 43 string is `F3 <size> <IP array> Mode=<1|2>`, where Mode 1 is Meraki and Mode 2 is Catalyst.

   a) To change the existing option 43 string `f104.ac10.0118` to `f305.ac10.0118.02`, do the following:

      - Change type from `f1` to `f3`,
      - Change length from `04` to `05`,
      - Add the sub-option `01` for Meraki or `02` for Catalyst.

   b) For controller discovery using DHCPv4, enter the following IOS/IOS XE configuration example:

```
ip dhcp pool vlan192
                                    network 192.168.200.0 255.255.255.0
                                    default-router 192.168.200.1
                                    option 43 hex hex f305.ac10.0118.02
```

   c) In the Windows server configuration, choose **DHCP** > **IPv4** > **Scope Options**.
   d) From the list of option names, select **043 Vendor Specific Info** and click **Configure Options**. The **Scope Options** window is displayed.
   e) Choose the **General** tab and check the **043 Vendor Specific Info** checkbox from the **Available Options**.
   f) Click **OK**.

   Note

   Ensure that at least one IP from the IP array is reachable through Internet Control Message Protocol (ICMP) or CAPWAP. The AP tries to contact the controller through pings. If the controller responds, the AP migrates to the controller management mode, otherwise the AP tries a CAPWAP discovery.

2. DHCPv6: The fast offline migration for DHCPv6 involves configuring Option 52 and Option 17.

   Note

   Configure Option 17, where the Enterprise ID is 29671, Subcode is 1, Mode is either 1 (Meraki), or 2 (Catalyst vendor-specific 29671). Option 52 (standard) is IPv6 array.

   a) In the Windows server configuration, choose **DHCP** > **IPv6** > **Scope Options**.
   b) From the list of option names, select **00052 capwap ac-address** and click **Configure Options**. The **Scope Options** window is displayed.
   c) Choose the **General** tab and select the **00052 capwap ac-address** checkbox from the **Available Options**.
   d) Click **OK**.
   e) To configure Option 17, choose **DHCP** > right-click **IPv6**, and select **Define Vendor Classes**. The **DHCP Vendor Classes** window is displayed.
   f) In the **DHCP Vendor Classes** window, create a new class.

g) In the **New Class** window, enter the **Display Name**, enter the **Vendor ID** as `29671`, and enter the **ASCII** value as `Cisco Wireless AP CW9178I`, for the CW9178I platform.

> **Note**
>
> For CW9176I and CW9176D1, use the following ASCII strings, respectively, `Cisco Wireless AP CW9176I` and `Cisco Wireless AP CW9176D1`.

h) Click **OK**.
i) Choose **DHCP** > right-click **IPv6**, and select **Set Predefined Options**.
The **Predefined Options and Values for v6** window is displayed.
j) In the **Predefined Options and Values for v6** window, click **Option Type**.
The **Option Type** window is displayed.
k) In the **Option Type** window, in the **Code** field, enter `1` and then click **OK**.
l) Click **OK**.
m) Choose **DHCP** > **IPv6** > **Scope Options** > **Configure Options**.
The **Scope Options** window is displayed.
n) In the **Scope Options** window, click the **Advanced** tab.
o) From the **Vendor class** list, select the vendor class.
p) From the **Available Options**, check the **00001 fast-conversion** checkbox.
q) In the **Data entry** section, in the **Byte** field, enter `0x2`.
r) Click **OK**.

> **Note**
>
> Ensure at least one IP from the IP array is reachable via Internet Control Message Protocol (ICMP) or CAPWAP. The AP tries to reach the controller through pings. If the controller responds, the AP migrates to the controller management mode, otherwise the AP tries a CAPWAP discovery.

The **00001 fast-conversion** option is added to the list of **Scope Options**.

3. DNSv4 and DNSv6: Fast offline migration using the migration string.
   a) Add a DNS record **cisco-automigrate.<domain>** in the DNS server.

   The AP checks for the **cisco-automigrate.<domain>** DNS entry.

   If the IP pings from DNS are successful, then the APs migrate immediately to the controller mode. If the pings fail, the AP tries the CAPWAP discovery method.

   > **Note**
   >
   > For this method to work correctly, the DHCP server must return the domain-name option (option 15) to the AP.

Successfully configuring fast offline migration ensures that APs migrate quickly to the new controller mode, maintaining network stability and performance.

Local status page

Describes the local status page.

For more information on how to access the local status page, refer to *Using the Cisco Meraki Device Local Status Page*.

Offline migration

The AP uses the traditional discovery mechanisms of DHCP, DNS and broadcast or multicast, if it is not able to reach the Meraki Cloud, perform a Fast Offline Migration, or migrate using the Local Status page.

Prevent false or accidental migration

The purpose of this task is to guide users on preventing accidental or unauthorized migration of APs to a controller, ensuring network stability and security.

To prevent accidental or false migration, perform these steps:

Procedure

1. Ensure that at least one IP in the IP address array returned by the DHCP option or the IP address of the resolved DNS entry is CAPWAP reachable. This CAPWAP response must include the controller version image for the CW917x AP to validate it and join the controller.
2. Enter cisco-do-not-automigrate when setting the DNS entry to resolve the controller's IP address. When it is resolved, the AP does not migrate to the controller mode.
3. You can configure commands to prevent the controller from responding to Day 0 CAPWAP discovery requests by CW917x APs. You can fine tune its configuration based on its own deployment specification. Configuration is done in the AP Join Profile.

   To prevent accidental or false migration, you must perform these configurations.

```
Device(config)# ap profile onboarding-prof
Device(config-ap-profile)# no capwap-discovery onboarding
Device(config-ap-profile)# exit
```

   To respond to the CAPWAP discovery, use the following configuration:

```
Device(config)# ap profile onboarding-prof
Device(config-ap-profile)# capwap-discovery ?
onboarding  Configure CAPWAP onboarding related parameters
private     Include private IP in CAPWAP Discovery Response
public      Include public IP in CAPWAP Discovery Response

Device(config-ap-profile)# capwap-discovery onboarding ?
all      Configure automatic CAPWAP onboarding from Meraki based on both
unicast and broadcast discovery request
unicast  Configure automatic CAPWAP onboarding from Meraki based on unicast
discovery request only
```

   By default the controller accepts only unicast requests for onboarding.

> **Note**
>
> If the CW917x APs have to be in the same subnet as the controller and use Broadcast (IPv4), or Multicast (IPv6) for discovery, then CAPWAP discovery onboarding should be set to **all**. Otherwise, the controller does not respond to Broadcast or Multicast discovery requests.

Completion of this task ensures that the APs are properly configured and do not unintentionally migrate to controller mode, preventing unauthorized network changes and maintaining system integrity.

Cisco regulatory domain

Details regulatory domain management for APs, providing guidance on country code assignment, best practices, examples of country code resolution, and step-by-step instructions for configuring and verifying regulatory activation via GUI and CLI.

Determining the regulatory domain is very important for wireless AP deployments. Unlike the mode of operation, which is a choice that can be made by the customers, provisioning the regulatory domain follows some strict rules and guidelines. With single PID, regulatory domain is automatically determined from where the APs are deployed.

Country code and regulatory domain

A country code is an identifier that enables Wi-Fi 7 APs to operate in compliance with the regulations of the country where they are deployed. Regulatory domains ensure that APs adhere to local compliance requirements through methods such as

- Compliance through geo-location: For APs operating in Meraki mode, regulatory standards are enforced using geo-location and network-wide settings.
- Hardware-independent enforcement: With certain AP models, such as the CW917x series, compliance is achieved through software rather than hardware-specific SKUs allowing worldwide deployment.

Regulatory domain information is determined based on the location and country where APs are deployed.

Determining AP Location

Various methods exist for determining the location of APs, which affect regulatory domain information.

- **Meraki determined location:** APs use IP addresses, shipping destinations, or dashboard configurations to reveal their location, essential for regulatory enforcement.
- **GPS or GNSS-based location:** If an AP is unable to identify the country-of-presence through Cisco cloud, the AP makes use of GPS or GNSS-based location. When the AP is located close to the open sky and there are enough satellites to get a location fix, the AP tries to use the satellites to locate country of operation.
- **Proximity-based AP location:** The proximity-based AP location method is useful for determining AP location based on proximity to other APs, especially when the APs are unable to find their location using the standard location techniques.

  For example, Anchored APs are APs that are closer to the periphery of a building and may be able to receive GPS signals, whereas the Non-Anchored APs are APs located in the middle of building, which may not be able to receive signals. The controller learns about the neighboring APs using radio resource management (RRM). Using RRM, you can propagate the location from the Anchored APs to the Non-Anchored APs.

This method is effective when the Wi-Fi 7 APs hear the Neighbor Discovery Protocols (NDPs) over 2.4 GHz from any other AP (Wi-Fi 7 or other APs) joined to the same controller.

Proximity-based location determination is faster compared to the other approaches, such as GPS or GNSS-based location.

- **AP Regulatory Activation File**: When automated methods are unsuccessful, a manual configuration via the appropriate activation file is implemented.

Best practices for Cisco regulatory domain

- In some deployment scenarios, without a clear sky view or with thick windows and neighboring buildings, the AP may take a long time or fail to obtain a GPS/GNSS signal. In such cases, other methods like Proximity, Migration, or Regulatory Activation File can be used to obtain the country code and regulatory information for the controller management mode.

  For greenfield deployments, we recommend that you use GPS/GNSS. Use Migration through Meraki Dashboard if you encounter issues obtaining the GPS/GNSS signal.

- For Cisco Wireless 9176I APs, configure the country code in the AP join profile to match the country code assigned through the Regulatory Activation File, proximity-based discovery, or GPS/GNSS. If the AP join profile does not include the matching country code, AP radios may remain operationally down or operate with limited functionality.

Examples of country code resolution

Gives the examples of country code resolution.

This section aims to provide detailed examples and explanations of the methods used by Wi-Fi 7 APs to determine and resolve their country codes, including GPS or GNSS-based location, proximity-based location, migration, and regulatory activation file methods.

These examples show how Wi-Fi 7 APs determine their country code:

- GPS or GNSS-based location: APs obtain geolocation via the integrated GPS or GNSS antenna. The CW917x series AP have a built-in GPS or GNSS. They can obtain the geolocation co-ordinates, as long as they can get a clear sky view, typically placed near a window, to obtain the satellite signal. The controller maps geolocation coordinates to the country. Until the AP obtains the country code, it will have **-UN** as the regulatory domain.

  For APs joining without domain the output displays **-UN** as the regulatory domain.

  For example, this **show** command displays the details of a Wi-Fi 7 AP which has the regulatory domain as -UN:

```
Device# show ap summary
Number of APs: 1
CC = Country Code
RD = Regulatory Domain

AP Name Slots AP Model  Ethernet MAC   Radio MAC      CC   RD   IP Address
   State         Location
-------------------------------------------------------------------------------
AP-B2E0   4   CW9178I   c414.a26f.b2e0 c414.a26f.b2f0 --   -UN  20.20.20.52
  Registered default location
```

  This **show** commands display the results after the controller determines the country code and the AP reloads and joins back with a country code:

```
Device# show ap name Wi-Fi7-AP-B2E0 config general | inc Country
Country Code                                    : US
Regulatory Domain Allowed by Country            : 802.11bg:-A 802.11a:-AB
```

```
802.11 6GHz:-B
AP Country Code                                 : US  - United States
Country Code Resolution Method                  : GPS

Device# show ap summary
Number of APs: 1
CC = Country Code
RD = Regulatory Domain
AP Name Slots AP Model  Ethernet MAC   Radio MAC      CC   RD   IP Address
   State         Location
-------------------------------------------------------------------------------
AP-B2E0   4   CW9178I   c414.a26f.b2e0 c414.a26f.b2f0 US   -B  20.20.20.52
 Registered default location
```

- Proximity-based AP location: For brownfield deployments, if your APs cannot obtain the GPS/GNSS signal due to existing legacy APs, use proximity-based discovery.

```
Device# show ap summary
Number of APs: 2
CC = Country Code
RD = Regulatory Domain
AP Name  Slots AP Model  Ethernet MAC  Radio MAC       CC   RD   IP Address
     State        Location
-------------------------------------------------------------------------------
AP-B2E0    4     CW9178I c414.a26f.b2e0 c414.a26f.b2f0 --   -UN  20.20.20.52
  Registered   default location
AP-E040    3     CW9176I 8c88.814f.e040 ecf4.0caf.6a60 US   -B   20.20.20.51
  Registered   default location
```

In the example above, the AP named AP-E040 has a country code and regulatory domain and the AP named AP-B2E0 that does not have a country code and regulatory domain, are in close proximity. AP-B2E0 learns its country code from AP-E040. The APs reload, after they learn their country code from the neighboring APs.

This example displays the state of the AP after obtaining the country code:

```
Device# show ap summary
Number of APs: 2
CC = Country Code
RD = Regulatory Domain
AP Name  Slots AP Model  Ethernet MAC  Radio MAC       CC   RD   IP Address
     State        Location
-------------------------------------------------------------------------------
AP-B2E0    4     CW9178I c414.a26f.b2e0 c414.a26f.b2f0 US  -B  20.20.20.52
 Registered   default location
AP-E040    3     CW9176I 8c88.814f.e040 ecf4.0caf.6a60 US  -B  20.20.20.51
 Registered   default location
```

```
C9800-L# show ap name Wi-Fi7-AP-B2E0 config general | inc Country
Country Code                                    : US
Regulatory Domain Allowed by Country            : 802.11bg:-A 802.11a:-AB
 802.11 6GHz:-B
AP Country Code                                 : US  - United States
Country Code Resolution Method                  : Proximity
```

- Migration: When you migrate APs from Meraki Dashboard, the APs keep their existing country code.

  For greenfield users, where

  - there are no legacy deployments,

- the deployment restrictions make it difficult to obtain the GPS or GNSS signal, and
- there is easy workflow of migrating the APs to the controller mode for Day 0, and obtaining country information,

we recommend the migration method.

This example displays the country code resolution method as Installed through Meraki Dashboard

```
Device# show ap name Wi-Fi7-AP-B2E0 config general | inc Country
Country Code                                    : US
Regulatory Domain Allowed by Country            : 802.11bg:-A  802.11a:-AB
802.11 6GHz:-B
AP Country Code                                 : US  - United States
Country Code Resolution Method                  : Installed via Meraki
Dashboard
```

- Regulatory Activation File: Download a Regulatory Activation File (RAF) from the Meraki Dashboard, that can be installed on the controller. See the section on Regulatory Activation File method for more details.

Regulatory activation file

The Cisco Meraki dashboard creates a regulatory activation file that has AP details such as the AP location, serial numbers, MAC addresses, country code, and site tags that can be imported to the controller through the Cisco Meraki Dashboard or saved to an external server or device.

To download the file from the Meraki Dashboard, choose **Meraki Dashboard** > **Network-wide** > **General** > **Regulatory info** > **Download regulatory file**.

> **Note**
>
> When you apply a new Regulatory Activation File (RAF), the new AP MAC-to-country mapping replaces the existing mapping. The contents of the new RAF overwrite the contents of the previously applied RAF; the mappings are not merged. Ensure that the new RAF contains all required AP mappings before applying it.

Configure AP regulatory activation (GUI)

Complete this task to activate the country code and regulatory domain of APs, which are in the worldwide mode.

This task guides you through the process of activating the regulatory domain on APs that have not been factory-programmed with a specific regulatory domain, using the GUI.

Complete this task to activate the country code and regulatory domain of APs, which are in the worldwide mode.

Before you begin

To provision a specific regulatory domain on APs that are not factory-programmed with a regulatory domain, download the regulatory activation file from the Meraki dashboard.

Procedure

1. Choose **Administration** > **Regulatory Activation**.
2. Click the upload area to select the regulatory activation file from your local folder, or, drag and drop the file into the upload area.

> **Note**
>
> Ensure that you add a new file every time regulatory activation has to be performed.

3. Click **Upload** to upload and validate the regulatory activation file.

   A message indicates the activation file has been validated. The records display the **AP MAC** details, **Country Code**, **Serial Number**, and the following validation results:

   - **Invalid Domain**: In this mode, APs do not have a country code, resulting in an undefined (UN) regulatory domain. The country code from the activation file is applied to APs that match this condition.
   - **Regulatory Mismatch**: In this mode, APs have a country code, but the country code is not configured on the controller.

     > **Note**
     >
     > To resolve a regulatory mismatch issue, enable the country code on the controller.

   - **Not World Wide Mode**: The APs in this mode are currently not affected by the regulatory activation process.

4. Click **Apply** to start the activation process.

   The activation process resolves the country code and regulatory domain of APs in Invalid Domain.

   A warning message is displayed that the regulatory activation process will cause the joined APs to be non-operational and hence get disconnected.

5. Click **OK** to start the process.

   The process runs in the background. A message is displayed if none of the records is impacted by the uploaded regulatory activation file.

The result of this task is that the APs are configured with the appropriate country code and regulatory domain, ensuring compliance and operational readiness.

What to do next

Go to the **Access Point Configuration** page to monitor the results.

Configure AP regulatory domain (CLI)

Describes the CLI steps to configure AP regulatory activation.

The purpose of this task is to guide users through the CLI commands necessary to configure AP regulatory activation, ensuring compliance with regional regulations.

Procedure

---

1. Enable privileged EXEC mode

Example

```
Device# enable
```

Enables privileged EXEC mode. Enter your password if prompted.

2. Apply the regulatory domain configuration

Example

```
Device# ap regulatory activation apply
```

Applies the regulatory domain configuration.

3. Clear all the AP MAC to country mapping records

Example

```
Device# ap regulatory activation clear all
```

Clears all the AP MAC to country mapping records or a specific AP MAC to country mapping record.

4. Configure the regulatory domain activation file

Example

```
Device# ap regulatory activation file reg-ap-act.json
```

Configures the regulatory domain activation file.

This configures the activation file necessary for domain settings.

What to do next

Verify that the AP regulatory domain configurations are operational and comply with regional requirements.

Verifying regulatory activation

This document provides verification details for the regulatory activation feature.

Describes the verification details of the regulatory activation feature.

Verifying Regulatory Activation Details for All APs

To verify regulatory activation details for all APs, run the following command:

```
Device# show ap regulatory activation all
Regulatory Activation file Meta-data
------------------------------------
Date Created     : 2024-06-28T08:55:13Z
Created By       : ciscoap.user@meraki.net/SSO
Device count     : 10
Organization Id  : 1130091

.
.
.
```

Verifying Regulatory Activation Details for Specific APs

To verify the regulatory activation details for specific APs, run the following command:

```
Device# show ap regulatory activation 38XX.79XX.9fXX
AP MAC          Serial Number         Country Code
-----------------------------------------------------
38XX.79XX.9fXX  Q3XX-XKXX-F3XX
```

E-Label display

Describes E-Label display features for APs, including compliance status monitoring for device models and configuration procedures using the GUI to ensure adherence to electronic labeling requirements.

E-LABEL compliance status

This topic describes the e-label compliance status.

A regulatory requirement for wireless APs is a set of standards that:

- mandates compliance with evolving legal or formal regulations,
- covers aspects such as operational frequencies and power levels, and
- include the implementation of technologies like the "E-label" for compliance.

Starting with the Cisco IOS XE 17.18.1 version, the E-Label digital labeling feature became accessible via the controller's GUI. This feature enables seamless integration of new regulatory approvals concerning the E-Label compliance without necessitating physical modifications to the devices.

Feature history for access point upgrade management enhancements
Table 25: Feature history

Release	Feature Information
Cisco IOS XE 17.18.1	The E-Label digital labeling feature is accessible via the controller's GUI and enables seamless integration of new regulatory approvals for wireless APs.

Starting with the Cisco IOS XE 17.18.1 release, this digital labelling feature is available via the controller's GUI, enabling seamless integration of new regulatory approvals without requiring physical modifications to the device.

E-Label compliance status of AP models

E-Label compliance status of AP models.

These are the AP models that support E-Label compliance status

- Cisco Catalyst Wi-Fi 6 APs
- Cisco Catalyst Wi-Fi 6E APs
- Cisco Catalyst Wi-Fi 7 APs

Wi-Fi Technology	AP Model
Cisco Catalyst Wi-Fi 6 APs	Cisco Catalyst 9105 AXI/AXW APs
	Cisco Catalyst 9115 AXI/AXE APs
	Cisco Catalyst 9117 AXI APs
	Cisco Catalyst 9120 AXI/AXE/AXP APs
	Cisco Catalyst 9130 AXI/AXE/AXE-STA APs
	Cisco Catalyst 9124 AXI/AXE/AXD APs
Cisco Catalyst Wi-Fi 6E APs	Cisco Catalyst 9136I APs
	Cisco Catalyst Wireless 9166I/D1 APs
	Cisco Catalyst Wireless 9164I APs
	Cisco Catalyst Wireless 9162I APs
	Cisco Catalyst Wireless 9163E APs
Cisco Catalyst Wi-Fi 7 APs	Cisco Catalyst Wireless 9178I APs
	Cisco Catalyst Wireless 9176I/D1 APs
	Cisco Catalyst Wireless 9172I/H APs

Configure AP E-Label compliance status (GUI)

This topic describes how to configure an AP E-Label compliance status using the GUI.

Ensure regulatory compliance of the AP E-Label by configuring its status through the GUI.

This task involves verifying the compliance status of an AP E-Label via the GUI.

To configure the AP E-Label compliance status, perform these steps

Procedure

1. Choose **Monitoring** > **Wireless** > **AP Statistics**.

> **Note**
>
> All the APs connected to the controller are automatically displayed.

2. Click the AP to view the regulatory compliance status.
3. Go to **360 View**.
4. Click the **Click here for Legal and Regulatory information**.

> **Note**
>
> This option will be under the **AP Country Code** detail.

A pop-up is displayed with the regulatory information for the selected AP, showing compliance details across various countries.

22 Countries and Regulations

Topics:

- Country codes
- Regulatory compliance domain
- Remove 8 channel restriction on slot 1 of Cisco Catalyst 9166 series APs
- Ensure 6 GHz radio band persistence after CAPWAP reset

Country codes

Explains how country codes enable wireless devices to comply with regulatory requirements specific to each country.

A country code is a regulatory identifier that

- specifies the country of operation for wireless devices, such as controllers and APs which must comply with varying regulatory requirements, and
- ensures each radio's broadcast frequency bands, interfaces, channels, and transmit power levels comply with country-specific regulations.

Each AP radio receives a regulatory domain at the factory, such as -E for Europe. Set the country code to match the location—for example, FR for France or ES for Spain.

Information About Japanese Country Codes

Country codes define the legal channels for each country. These country codes are available for Japan:

- J2: which allows only -P radios to join the controller, and
- J4: which allows 2.4GHz JPQU and 5GHz PQU to join the controller.

Prerequisites for configuring country codes

Prerequisites for configuring country codes.

- Generally, you should configure one country code per device. Select a country code that matches where the device and its APs are physically located. You can configure up to 200 country codes per device. You can manage APs in different countries from one device using multiple-country support.
- If you use the multiple-country feature, configure all devices joining the same RF group with the same countries in the same order.
- Each AP uses all available legal frequencies, but it is assigned frequencies approved for its domain.
- The RF group leader's country list decides which channels are available for group members. The RF group leader's country list does not depend on the countries on group members.
- If your device is in the Japan regulatory domain, configure at least one Japan country code (JP, J2, or J3) before the most recent boot.
- For devices in the Japan regulatory domain, you should have one or more Japan country codes (J2, or J4) configured on your device at the time of the most recent boot.
- For devices in the Japan regulatory domain, you must have at least one access point with a -J regulatory domain joined to your device.
- You cannot delete a country code with the **wireless country country-code** command if you configured it with the **ap country list** command. You also cannot delete a country code using the **ap country list** command if you configured it with the **wireless country country-code** command.

Configure country codes (GUI)

Configure country codes using GUI.

Set the allowed country codes on wireless APs to comply with local regulations.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points** > **Country**.
2. On the **Country** page, check the check box for each country where your APs are installed. If you select more than one check box, a message displays that RRM channels and power levels are limited to common channels and power levels.
3. Click **Apply**.

Configure country codes (CLI)

Configure country codes using commands.

Assign and verify country codes on an AP or wireless controller to ensure regulatory compliance for wireless operation.

Procedure

1. Display the list of all the available country codes.

   Example

   ```
   Device# show wireless country supported
   ```

2. Enter the global configuration mode and disable the 802.11b/g network, if you use 24GHz, 5GHz or 6GHz.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# ap dot11 {24ghz | 5ghz| 6ghz} shutdown
   ```

3. Assign APs to a specific country.

   Example

   ```
   Device(config)# ap country country_code IN
   ```

   Configure the country code on the controller so that APs joining the controller match the country code and the corresponding regulatory domain codes for the AP.

   Note

   You can configure more than one country code.

4. Configure 200 country codes per device.

   Example

   ```
   Device(config)# wireless country country_code IN
   ```

> **Note**
>
> Use this command for deployments with more than 20 countries.

5. Return to the privileged EXEC mode and display the configured countries.

   Example

```
Device(config)# exit
```

```
Device# show wireless country configured
```

6. Display the list of available channels for the country codes configured on your device and enter the global configuration device.

   Example

```
Device# show wireless country channels
```

> **Note**
>
> Complete the next three steps only if you have configured multiple country codes in step 6.

7. Enter the global configuration mode and enable the 802.11b/g network, if you use 24GHz, 5GHz or 6GHz. Return to the privileged EXEC mode and disable the AP.

   Example

```
Device# configure terminal
```

```
Device(config)# no ap dot11 {24ghz | 5ghz| 6ghz} shutdown
```

```
Device(config)# end
```

```
Device# ap name cisco-ap AP02 shutdown
```

> **Note**
>
> Make sure to disable only the AP that you are configuring with country codes.

8. Enter the global configuration mode and assign each AP with a country code from the controller country code list.

Example

```
Device# configure terminal
```

```
Device# ap name cisco-ap AP02 country country_code US
```

> **Note**
>
> - Ensure that the country code that you choose is compatible with the regulatory domain of at least one of the APs radios.
> - Disable the AP before changing its country code.

9. Return to privileged EXEC mode and enable the AP.

Example

```
Device(config)# end
```

```
Device# ap name cisco-ap AP02 no shutdown
```

Configuration examples for configuring country codes

Configuration examples for configuring country codes.

View channel list for country codes

View channel list for country codes details.

This example shows how to display the list of available channels for the country codes on your devicedevice:

```
DeviceDevice# show wireless country channels

Regulatory compliance domain

Explains how regulatory compliance domains determine country-specific wireless operating parameters and streamline AP configuration.

A regulatory domain is a set of country-specific rules that

- are designed for use in multiple countries with varying regulatory requirements
- enables you to specify a particular country of operation, such as FR for France or ES for Spain, and
- ensures that each radio's broadcast frequency bands, interfaces, channels, and transmit power levels comply with country-specific regulations.

This feature reduces the number of regulatory domains by updating the pre-provisioned domains workflow. It determines the regulatory domain at runtime for each country code. The new Rest of World (RoW) domain includes the nine earlier domains. Each AP selects its regulatory domain from these options by referencing the regulated power table and allowed radio channels.

The transmission power value in the TPC IE of the beacon may differ from the AP's transmission power value by up to 2 dB. You can check this difference by using the **show controllers dot11radio** command. The maximum allowed deviation in the TPC IE of the beacon is two dB.

Global country-level domains

This topic lists detailed information about the power table and supported channels of countries in the global domain for 2.4GHz, 5GHz, 6GHz, and Rest of World domains.

- Use this information to determine the allowed configurations for each region.
- For additional technical details and Rest of World/6GHz support, see the Cisco Catalyst 9100AX Access Points Technical Reference.
- For more information about country phase and codes, refer to Cisco CW917x Wi-Fi 7 Access Point Country Codes and Phases.

Remove 8 channel restriction on slot 1 of Cisco Catalyst 9166 series APs

Explains channel restrictions on the XOR radio in Cisco Catalyst 9166 Series APs and how dynamic switching impacts channel availability based on region and device mode.

A channel restriction on an XOR radio is a regulatory and configuration constraint that

- limits the number of usable channels on the 5GHz or 6GHz bands based on region and device mode
- dynamically adjusts channel availability and power settings according to band selection and regional compliance, and

- enables optimized performance and access to all channels in supported configurations.

Starting with Cisco Catalyst IOS XE 17.12.5 release, you can restrict channels on slot 1 of Cisco Catalyst 9166 Series APs.

The Cisco 9166 Series AP includes dynamic XOR 5GHz or 6GHz radio band switching that optimizes performance and ensuring regulatory compliance. During startup, the XOR radio defaults to the 5GHz band in regions where 6GHz is not supported. Otherwise, it defaults to 6GHz. The AP actively adjusts and communicates channel power settings. It offers all full 5GHz channels when configured for 6GHz and restricted channels when in 5GHz mode.

The XOR radio infrastructure manages channel power payload adjustments when users switch between the 5GHz and 6GHz bands. The XOR radio can function as either a single 5GHz or a dual 5GHz setup. When operating in a single 5GHz mode, the AP provides a complete list of 5GHz channels available in the selected country. In dual 5GHz mode, the system configures and communicates channel power settings. It offers full 5GHz channels in one slot and restricted channels in the other.

Note

If 6GHz is not supported in your country, use slot 2 in either 5GHz or 6GHz. Configure the AP to Client serving mode to prevent resets.

For 6G unsupported countries, you must use slot 1 as a full band and configure slot 2 to 6GHz in Client serving mode.

Configure XOR 5/6GHz radio slot for 6GHz band (CLI)

Assign the 6GHz band to the XOR 5/6GHz radio slot on an access point to support Wi-Fi 6E clients.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Disable dual-band radio hosted on slot 2 for a specific AP.

   Example

   ```
   Device# ap name ap-name AP-SIDD-A06 dot11 dual-band slot 2 shutdown
   ```

   ```
   Device# ap name ap-name AP-SIDD-A06 [no] dot11 dual-band slot 2 shutdown
   ```

   Use the **no** form of this command to enable the dual-band radio.

3. Configure the dual-band role in client-serving mode.

   Example

   ```
   Device# ap name ap-name AP-SIDD-A06 dot11 dual-band slot 2 radio role manual
    client-serving
   ```

4. Configure the 802.11 dual-band radio's current band to 6Ghz.

   Example

```
Device# ap name ap-name AP-SIDD-A06 dot11 dual-band slot 2 band 6ghz
```

Ensure 6 GHz radio band persistence after CAPWAP reset

Configure the AP radio role to ensure the 6 GHz band remains active after a CAPWAP reset.

This procedure describes how to configure the AP radio role to manual for slot 2. This change ensures that the 6 GHz radio band remains active, even after a CAPWAP reset. If the radio role is set to auto, the AP might revert to the 5 GHz band upon reset.

Before you begin

Ensure you have CLI access to the AP.

Procedure

1. Verify the current radio role configuration. From the AP CLI, check the current radio configuration for slot 2.

   Example

```
show capwap client config | i Radio
```

   If the output shows the radio role for slot 2 as auto, proceed to Step 2.

   If the output shows the radio role for slot 2 as manual, no further action is required for this setting

2. Configure the radio role to manual and set the 6 GHz band. Execute these commands on the AP CLI to set the radio role for slot 2 to manual and configure it for the 6 GHz band. This step ensures the controller applies the manual radio role to the AP.

   Example

```
ap name NAME dot11 dual-band slot 2 shutdown
ap name NAME dot11 dual-band slot 2 radio role manual client-serving
ap name NAME dot11 dual-band slot 2 band 5ghz
ap name NAME dot11 no dual-band slot 2 shutdown
ap name NAME dot11 dual-band slot 2 shutdown
ap name NAME dot11 dual-band slot 2 band 6ghz
```

23 Security

Topics:

- Data Datagram Transport Layer Security
- 802.1X authentication
- Access point client ACL counters
- AP MAC authorization

Data Datagram Transport Layer Security

Introduces 802.1X authentication, outlining its security functions, supported EAP methods, integration with Cisco devices, feature history, and requirements for AP credential provisioning and authentication processes on Wave 2 and Wi-Fi 6 APs.

A data Datagram Transport Layer Security (DTLS) is a security protocol that

- encrypts CAPWAP data packets sent between an access point and a controller
- uses separate UDP ports for control (5246) and data (5247) packets,
- is a standards-track IETF protocol that can encrypt both control and data packets based on TLS, and
- supports v1.2 as the latest version available.

Feature history for data DTLS

Feature name	Release information	Feature description
Data Datagram Transport Layer Security	Cisco IOS XE Gibraltar 16.7.1	The data Datagram Transport Layer Security (DTLS) is a standards-track IETF protocol that can encrypt both control and data packets based on TLS.

CAPWAP control and data packets

CAPWAP control packets are management packets that are exchanged between a controller and an AP. CAPWAP data packets encapsulate forwarded wireless frames.

If an AP does not support DTLS data encryption, DTLS is enabled only for the control plane, and a DTLS session for the data plane is not established.

DTLS handshake

If an AP supports Data DTLS

- It enables data DTLS after receiving the new configuration from the controller
- The AP performs a DTLS handshake on port 5247 and after successfully establishing the DTLS session, and
- All the data traffic (from the access point to the controller and the controller to the access point) is encrypted.

Note

The throughput is affected for some APs that have data encryption enabled.

The controller does not perform a DTLS handshake immediately after processing client-hello with a cookie, if the following incorrect settings are configured:

- ECDHE-ECDSA cipher in **ap dtls-cipher** and RSA-based certificate in “wireless management trustpoint”.
- RSA cipher in **ap dtls-cipher** and EC-based certificate in “wireless management trustpoint”.

This is applicable when you move from CC > FIPS > non-FIPS mode.

> **Note**
>
> If the DHCP lease time of the AP is less and the DHCP pool is small, the AP join may fail or a failure in establishing the Data Datagram Transport Layer Security (DTLS) session may occur. In such scenarios, associate the AP with a named site-tag and increase the DHCP lease time for at least eight days.

Configure data DTLS (GUI)

Complete this task to enable DTLS data encryption for the APs on the controller.

Procedure

1. Click **Configuration** > **Tags and Profile** > **AP Join**.
2. Click **Add** to create a new **AP Join Profile** or click an existing profile to edit it.
3. Click **CAPWAP** > **Advanced**.
4. Check **Enable Data Encryption** check box to enable Datagram Transport Layer Security (DTLS) data encryption.
5. Click **Update & Apply to Device**.

The DTLS data encryption for the APs on the controller is enabled.

Configure data DTLS (CLI)

Configure Data DTLS using commands.

Complete this task to enable DTLS data encryption for the access points on the controller.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

   > **Note**
   >
   > Use the default AP profile (default-ap-profile) or create a named AP profile, as shown in the example.

3. Enable link encryption on your profile.

Example

```
Device(config-ap-profile)# link-encryption
```

Answer **Yes**, when the system prompts you with this message:

```
Enabling link-encryption will reboot the APs with link-encryption.
                         Are you sure you want to continue? (y/n)[y]:
```

> **Note**
>
> If you set stats-timer as zero (0) under the AP profile, then the AP will not send the link encryption statistics.

4. Return to privileged EXEC mode.**end**

Example

```
Device(config-ap-profile)# end
```

5. Optional: Display the DTLS session established for the AP that has joined this controller.

Example

```
Device# show wireless dtls connections
```

6. Optional: Display the link encryption-related statistics (whether link encryption is enabled or disabled) counter received from the AP.

Example

```
Device# show ap link-encryption
```

The DTLS data encryption for the access points on the controller is now enabled.

```
Device# configure terminal
Device(config)# ap profile ap-profile-name
Device(config-ap-profile)# link-encryption
Device(config-ap-profile)# end
Device# show wireless dtls connections
Device# show ap link-encryption
```

802.1X authentication

Introduces 802.1X authentication, outlining its security functions, supported EAP methods, integration with Cisco devices, feature history, and requirements for AP credential provisioning and authentication processes on Wave 2 and Wi-Fi 6 APs.

IEEE 802.1X port-based authentication is a network security protocol that

- prevents unauthorized devices from accessing the network
- utilizes EAP authentication models to ensure secure communication, and
- integrates with devices like routers, switches, and access points based on configuration.

Feature history

Table 26: Feature history for 802.1X authentication

Feature name	Release information	Feature description
802.1X authentication	Cisco IOS XE 16.9.1	IEEE 802.1X port-based authentication is a network security protocol that utilizes EAP authentication models to ensure secure communication, and integrates with devices like routers, switches, and access points based on configuration.
Access ports with dual port authentication	Cisco IOS XE 17.17.1	The access ports with dual port authentication feature supports dual Ethernet ports on Cisco Catalyst 9136 APs and Cisco Wireless 9178I APs.

Currently, Cisco Wave 2 and Wi-Fi 6 (802.11AX) APs support 802.1X authentication with switch ports for EAP-FAST, EAP-TLS, and EAP-PEAP methods. Configuration and credential provision to APs can be done through the controller.

Note

If the AP is dot1x EAP-FAST, upon reboot, it should perform an anonymous PAC provision using ADH cipher suites to establish an authenticated tunnel. Authentication will fail if RADIUS servers do not support ADH cipher suites.

EAP-FAST protocol

Details of the EAP-FAST protocol.

In the EAP-FAST protocol developed by Cisco, to establish a secured TLS tunnel with RADIUS, the AP requires a strong shared key (PAC), provided via in-band or manual out-band provisioning.

- The EAP-FAST type configuration requires 802.1x credentials configuration for AP, since AP will use EAP-FAST with MSCHAP Version 2 method.
- Cisco 7925 phones do not support Local EAP.
- In Cisco Wave 2 APs, for 802.1x authentication using EAP-FAST after PAC provisioning (caused by the initial connection or after AP reload), ensure that you configure the switch port to trigger re-authentication using **authentication timer restart** *num* or **authentication timer reauthenticate** *num*.
- Starting from Cisco IOS XE Amsterdam 17.1.1, TLS 1.2 is supported in the EAP-FAST authentication protocol that requires strong security measures.

EAP-TLS/EAP-PEAP Protocol

Details about

The EAP-TLS protocol or EAP-PEAP protocol provides certificate based mutual EAP authentication.

In EAP-TLS, both the server and the client side certificates are required, where the secured shared key is derived for the particular session to encrypt or decrypt data. In EAP-PEAP, only the server-side certificate is required, and the client authenticates using a password-based protocol in a secured channel.

The EAP-PEAP type configuration requires Dot1x credentials configuration for the AP, and the AP also needs to go through LSC provisioning. AP uses the PEAP protocol with MSCHAP Version 2 method.

Access ports with dual port authentication

This section introduces the access ports that have dual port authentication.

The access ports with dual port authentication feature supports dual Ethernet ports on Cisco Catalyst 9136 APs and Cisco Wireless 9178I APs.

The access ports with dual port authentication feature

- Enhances network security and provides redundancy through 802.1x and MAC Authentication Bypass (MAB).
- Ensures high-availability and minimizes downtime.
- Supports authentication methods including EAP-FAST, EAP-PEAP, and EAP-TLS.
- Handles certificate distribution for secure connections on both ports.

Prerequisites for access ports with dual authentication

This topic describes the prerequisites for access ports with dual authentication.

Prerequisites for access ports with dual authentication support include:

- Enable dot1x on the switch port whenever dot1x credentials are configured on the controller. Ensure that dot1x credentials are configured on the controller and also on the switch port.
- Clear the user credentials to propagate the correct configuration on the AP,when dot1x is disabled.
- Modify the configuration on the controller, and then on the switch port, to avoid configuration mismatch on the AP when dot1x is enabled or disabled. Use the AP dot1x command for recovery.
- For APs with dual Ethernet ports, configure the connected switch port to allow authentication and authorization for both AP Ethernet MAC addresses. You can use one of these methods based on your site security policy:
  - Configure multi-host mode on the switch port.
  - Configure multi-auth mode and use MAC Authentication Bypass (MAB) for the AP MAC address on the Ethernet port that does not perform 802.1X authentication.
  - Configure multi-auth mode and use RADIUS authorization to apply a template that changes the switch port to multi-host mode after the AP successfully completes 802.1X authentication. The template can be pushed only for AP models that use dual Ethernet.
  - Starting with AP software Release 26.2.1, configure **access-session host-mode multi-host peer** on both switch ports connected to a dual Ethernet AP. The **peer** keyword is required for successful AP authentication. Update the switch-port configuration or the RADIUS authorization template before upgrading the AP.

802.1X authentication limitations

802.1X authentication limitations.

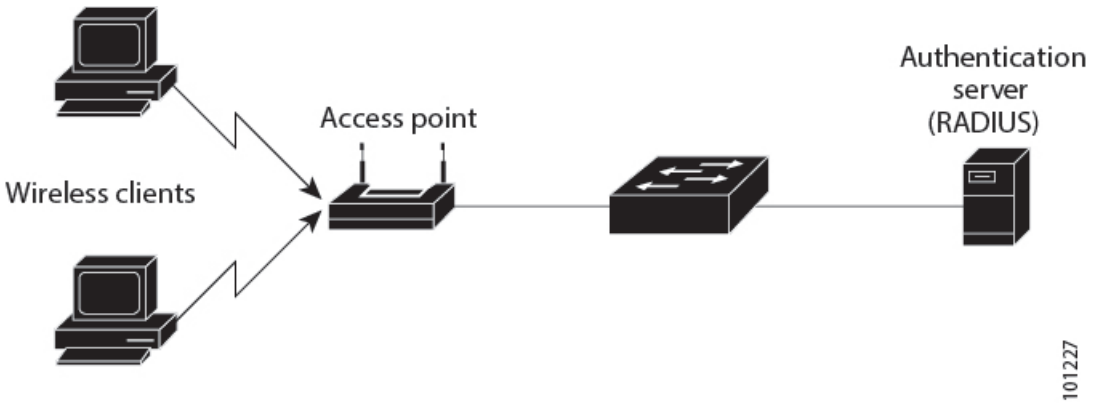
The 802.1X authentication limitations are:

- An AP loses its 802.1X credentials and configuration when migrating from a Cisco AireOS controller to a Cisco Catalyst 9800 controller. To rest ore them, the AP must join the new Catalyst 9800 controller. The controller pushes the necessary credentials and configuration for authentication on the switchport. You can either temporarily disable 802.1X authentication on the switchport to allow the AP to connect and receive its configuration, or use MAC Authentication Bypass (MAB) to provide network access to the AP for staging. After staging, you need to reload the AP or restart 802.1X authentication on the switch to complete the setup.
- 802.1X is not supported on dynamic ports or Ethernet Channel ports.
- 802.1X is not supported in a mesh AP scenario.
- There is no recovery from the controller on credential mismatch or the expiry/invalidity of the certificate on AP. The 802.1X authentication has to be disabled on the switch port to connect the AP back to fix the configurations.
- There are no certificate revocation checks implemented on the certificates installed in AP.
- You can provision only one Locally Significant Certificate (LSC) for the AP. Use the same certificate for both CAPWAP DTLS session establishment and 802.1X authentication with the switch. If you disable the global LSC configuration on the controller, the AP deletes the already provisioned LSC.
- If the AP has clear configurations applied, it will lose the 802.1X EAP Type configuration and the LSC Certificates. The AP should undergo the staging process again if 802.1X is required.
- 802.1X for trunk port APs on multi-host authentication mode is supported. Network Edge Authentication Topology (NEAT) is not supported on COS APs.
- The DHCP requests are sent in incremental periodic value of: "2, 3, 4, 6, 8, 11, 15, 20, 27, 30, 30, 30, 30, 30...". The Cisco Catalyst 9100 Access Points perform an interface reset after a 100-second timeout, which in turn resets the timers on the associated switch port to which they are connected.

Topology

Topology details

This topic explains how an AP acts as an 802.1X supplicant and how a switch uses a RADIUS server that supports EAP-FAST, EAP-TLS, and EAP-PEAP to authenticate it.



Summary

When dot1x authentication is enabled on a switch port, the connected device must authenticate itself to send and receive data other than 802.1X traffic.

- For EAP-FAST authentication, configure the RADIUS server's credentials at the controller and pass them to the AP through a configuration update request.
- For EAP-TLS or EAP-PEAP, the APs use certificates provided by the local CA server.

Workflow

Figure 4: Topology for 802.1X authentication

Configuring 802.1X authentication type and LSC AP authentication type (GUI)

Configuring 802.1X Authentication Type and LSC AP Authentication Type using GUI.

Complete this task to configure 802.1X authentication type and LSC AP authentication type.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join Profile** page, click **Add**.

   The **Add AP Join Profile** page is displayed.
3. In the **AP** > **General** tab, navigate to **AP EAP Auth Configuration**.
4. From the **EAP Type** drop-down list, choose the EAP type as **EAP-FAST**, **EAP-TLS**, or **EAP-PEAP** to configure the dot1x authentication type.
5. From the **AP Authorization Type** drop-down list, choose either **CAPWAP DTLS +** or **CAPWAP DTLS**.
6. Click **Save & Apply to Device**.

The 802.1X authentication type and LSC AP authentication type are configured.

Configure 802.1X authentication type and LSC AP authentication type (CLI)

Configure 802.1X authentication type and LSC AP authentication type using commands.

Complete this task to configure 802.1X authentication type and LSC AP authentication type.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Specify a profile name.

Example

```
Device(config)# ap profile ap-profile-name
```

3. Configure the dot1x authentication type.

   Example

   ```
   Device(config-ap-profile)# dot1x {max-sessions | username | eap-type |
   lsc-ap-auth-state}
   ```

   Here

   - **max-sessions**: Configures the maximum 802.1X sessions initiated per AP.
   - **username**: Configures the 802.1X username for all APs.
   - **eap-type:**: Configures the dot1x authentication type with the switch port.
   - **lsc-ap-auth-state**: Configures the LSC authentication state on the AP.

4. Configure the dot1x authentication type as EAP-FAST, EAP-TLS, or EAP-PEAP.

   Example

   ```
   Device(config-ap-profile)# dot1x eap-type {EAP-FAST | EAP-TLS | EAP-PEAP}
   ```

5. Configure the LSC authentication state on the AP.

   Example

   ```
   Device(config-ap-profile)# dot1x lsc-ap-auth-state {CAPWAP-DTLS |
   Dot1x-port-auth | Both}
   ```

   Here

   - **CAPWAP-DTLS**: Uses LSC only for CAPWAP DTLS.
   - **Dot1x-port-auth**: Uses LSC only for dot1x authentication with port.
   - **Both**: Uses LSC for both CAPWAP-DTLS and Dot1x authentication with port.

6. Exit the AP profile configuration mode and enter the privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

The 802.1X authentication type and LSC AP authentication type have been configured.

```
Device# configure terminal
Device(config)# ap profile ap-profile-name
Device(config-ap-profile)# dot1x eap-type
Device(config-ap-profile)# dot1x eap-type EAP-TLS
Device(config-ap-profile)# dot1x lsc-ap-auth-state Dot1x-port-auth
Device(config-ap-profile)# end
```

Configure the 802.1X username and password (GUI)

Describes the GUI steps to configure the 802.1X username and password.

Complete these steps to configure the 802.1X username and password.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join** page, click the name of the AP Join profile or click **Add** to create a new one.
3. Click the **Management** tab and then click **Credentials**.
4. Enter the local username, password details, and choose the appropriate local password type.
5. Enter 802.1X username and password details.
6. Choose the appropriate 802.1X password type.
7. Enter the time in seconds after which the session should expire.
8. Enable local credentials or 802.1X credentials, or both, as required.
9. Click **Update & Apply to Device**.

The configuration of the 802.1X username and password is complete.

Configure the 802.1X username and password (CLI)

Describes the steps to configure the 802.1X username and password.

Complete these steps to configure the 802.1X username and password.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify a profile name for the AP.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Configure the dot1x authentication type.

   Example

   ```
   Device(config-ap-profile)# dot1x {max-sessions | username | eap-type |
   lsc-ap-auth-state}
   ```

   Here

   - **max-sessions**: Configures the maximum 802.1X sessions initiated per AP.
   - **username**: Configures the 802.1X username for all APs

- **eap-type:**: Configures the dot1x authentication type with the switch port.
- **lsc-ap-auth-state**: Configures the LSC authentication state on the AP.

4. Configure the dot1x password for all the APs.

Example

```
Device(config-ap-profile)# dot1x username username password {0 | 8} password
```

Here

- **0**: Specifies an unencrypted password will follow.
- **8**: Specifies an AES encrypted password will follow.

The configuration of the 802.1X username and password is complete.

```
Device# configure terminal
Device(config)# ap profile ap-profile-name
Device(config-ap-profile)# dot1x eap-type
Device(config-ap-profile)# dot1x username username password 0 password
```

Enable 802.1X on the switch port (CLI)

Describes the steps to enable 802.1X on the switch port.

Complete these steps to enable 802.1X on the switch port.

Procedure

---

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Enable AAA.

Example

```
Device(config)# aaa new-model
```

3. Create authentication methods to determine user privilege for accessing the privileged command level, enabling the device to communicate with the AAA server.

Example

```
Device(config)# aaa authentication dot1x {default | listname}
method1[method2...]
```

4. Enable AAA authorization for network services on 802.1X.

Example

```
Device(config)# aaa authorization network group
```

5. Enable 802.1X port-based authentication, globally.

   Example

   ```
   Device(config)# dot1x system-auth-control
   ```

6. Enter the interface configuration mode and specify the interface to be enabled for 802.1X authentication.

   Example

   ```
   Device(config)# interface type slot/port
   ```

7. Enable 802.1X port-based authentication on the interface.

   Example

   ```
   Device(config-if)# authentication port-control {auto | force-authorized |
   force-unauthorized}
   ```

   Here are the options:

   - **auto**: Enables IEEE 802.1X authentication and causes the port to begin in the unauthorized state, allowing only EAPOL frames to be sent and received through the port. The authentication process begins when the link state of the port changes from down to up or when an EAPOL-start frame is received. The Device requests the identity of the supplicant and begins relaying authentication messages between the supplicant and the authentication server. Each supplicant attempting to access the network is uniquely identified by the Device by using the supplicant MAC address.
   - **force-authorized**: Disables IEEE 802.1X authentication and causes the port to change to the authorized state without any authentication exchange required. The port sends and receives normal traffic without IEEE 802.1X-based authentication of the client. This is the default setting.
   - **force-unauthorized**: Causes the port to remain in the unauthorized state, ignoring all attempts by the supplicant to authenticate. The Device cannot provide authentication services to the supplicant through the port.

8. Enable 802.1X authentication on the port with default parameters.

   Example

   ```
   Device(config-if)# dot1x pae [supplicant | authenticator | both]
   ```

9. Enter the privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

802.1X is enabled on the switch port.

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authentication dot1x default group radius
Device(config)# aaa authorization network group
Device(config)# dot1x system-auth-control
Device(config)# interface fastethernet2/1
Device(config-if)# authentication port-control auto
Device(config-if)# dot1x pae authenticator
Device(config-if)# end
```

Verify 802.1X on the switch port

To display the authentication state of 802.1X on the switch port, use the following command:

```
Device# show dot1x all
Sysauthcontrol              Enabled
Dot1x Protocol Version      2
Dot1x Info for FastEthernet1
-----------------------------------
PAE                         = AUTHENTICATOR
PortControl                 = AUTO
ControlDirection            = Both
HostMode                    = MULTI_HOST
ReAuthentication            = Disabled
QuietPeriod                 = 60
ServerTimeout               = 30
SuppTimeout                 = 30
ReAuthPeriod                = 3600 (Locally configured)
ReAuthMax                   = 2
MaxReq                      = 2
TxPeriod                    = 30
RateLimitPeriod             = 0
```

Verify the authentication type

To display the authentication state of an AP profile, use the following command:

```
Device#show ap profile default-ap-profile detailed
        AP Profile Name        : default-ap-profile
        Description            : default ap profile
        …
        Dot1x EAP Method       : [EAP-FAST/EAP-TLS/EAP-PEAP/Not-Configured]
        LSC AP AUTH STATE      : [CAPWAP DTLS / DOT1x port auth / CAPWAP DTLS
 + DOT1x port auth
```

Verify access ports dual port authentication

This section gives the details about the verification of access ports dual port authentication.

Verify access ports dual port authentication

To verify access ports dual port authentication, use the following commands:

```
Device# show ap profile name default-ap-profile detailed
AP Profile Name               : default-ap-profile
Description                   : default ap profile
```

```

Access point client ACL counters

Explains the AP Client ACL Counter feature that provides statistical counts for client ACL rules.

An access point client ACL counter is a statistical tracking feature that

- provides a count for client ACL rules to determine which rule was passing or dropping packets
- enables counting of packets that hit a specific rule in the client ACL, and
- is supported in FlexConnect mode and local switching central authentication sub-mode.

AP commands for ACL counter management

Use these AP commands to enable and manage the counter in the AP:

- **[no] debug flexconnect access-list counter [all | vlan-ACL | client-ACL]**
- **[no] debug flexconnect access-list event [all | vlan-ACL | client-ACL]**

To clear ACL counters use this command:

- **clear counters access-list client** *<MAC>* **all**

> **Note**
>
> This feature is available from the Cisco IOS XE Dublin 17.13.1 release. Until the Cisco IOS XE Dublin 17.12.1 release, there was no per-rule counter to determine which rule was passing or dropping the packets.

Feature history for Access Point Client ACL Counter

Lists the release and related information for the Access Point Client ACL Counter feature.

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 27: Feature History for Access Point Client ACL Counter

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.13.1	Access Point Client ACL Counter	The AP Client ACL Counter feature provides a statistical count for client ACL rules. This feature allows you to count the number of packets that hit a specific rule in the client ACL.

AP MAC authorization

This topic describes AP MAC authorization.

AP MAC authorization is a security feature that:

- ensures only authorized APs can associate with the controller,
- requires registration of the AP's Ethernet MAC address, and
- it is configured locally on the controller or on an external RADIUS server.

With the Cisco IOS-XE 17.18 release, APs support MAC address authorization using different delimiter formats to enhance the controller's support, which previously did not accept any delimiter.

IOS AAA config **mac-delimiter and subscriber mac-filtering security-mode** <> under AAA group server RADIUS is enabled for this feature for wireless AP join cases.

Note

To authenticate an AP using its MAC address:

- Set the *mac-filter* flag to **yes**. This setting configures AAA to send the username with the specified delimiter and sets the MAC filter flag.
- Configure AAA server groups that include the IP addresses of the selected server hosts. This configuration allows you to group existing server hosts, select a subset of the configured server hosts, and use them for a particular service.
- By arranging server groups and configuring them using the global server-host list, you can manage services with a more structured and secure approach.

Feature history for AP MAC authorization

AP MAC authorization feature history.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 28: Feature history for access point upgrade management enhancements

Release	Feature Information
Cisco IOS XE 17.18.1	AP MAC authorization enables APs to gain support for MAC address authorization using various delimiter formats. The feature improves the controller's support for this security feature. To enable this functionality for wireless AP join cases, the **mac-delimiter** and **subscriber mac-filtering security-mode** configurations under the AAA group server RADIUS are utilized.

Create a AAA RADIUS server (GUI)

This topic describes how to create a AAA RADIUS server using the GUI.

Configure a AAA RADIUS server using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **Server Groups** > **RADIUS**.
2. Click the **Add** button.
   The **Create AAA Radius Server Group** dialog box is displayed.
3. Enter a name for the RADIUS server in the **Name** field.
4. Enter the IPv4/IPv6 server address in the **Server Address**.
5. Optional: Choose **Clear Text** from the **Key Type** drop-down list.
6. Add **Key**.

> **Note**
>
> If global encryption is enabled, then all keys or passwords are encrypted.

7. Match the **Key** with the **Confirm Key** field.
8. Click **Apply to Device**.

Configure a AAA RADIUS server (CLI)

This topic describes how to configure a AAA RADIUS server using the CLI.

Configure a AAA RADIUS server using the CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RADIUS server name to enter the RADIUS server configuration mode.

   Example

   ```
   Device(config)# radius server ISE
   ```

   ISE is the user-defined string.

   a) Specify the RADIUS server parameters.

      Example

      ```
      Device(config-radius-server)# address ipv4 209.165.201.1 auth-port 1812
      acct-port 1813
      ```

      For **auth-port** port number, specify the UDP destination port for authentication requests. The range is from 0 to 65536 and the default is 1812.

      For **acct-port** port number, specify the UDP destination port for accounting requests. The default is 1813.

   b) Configure the RADIUS per-server encryption key.

      Example

      ```
      Device(config-radius-server)#  key rad123
      ```

3. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-sg-radius)# end
```

Create a AAA Group configuration (GUI)

This topic describes how to create a AAA Group configuration using the GUI.

Create a new AAA group using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **Server Groups** > **RADIUS** > **Server Groups**.
2. Click the **Add** button.
   The **Create AAA Radius Server Group** dialog box is displayed.
3. Enter a name for the RADIUS server in the **Name** field.
4. Add RADIUS as **Group Type**.
5. Select a **MAC-Delimiter** from the drop-down list.

   The available options are **colon**, **hyphen**, **single-hyphen**, and **none**.
6. Select **MAC-Filtering** from the drop-down list.

   The available options are **mac**, **key**, and **none**. The option **none** is supported only when both **MAC-Delimiter** and **MAC-Filtering** are set to the same value.
7. Add the newly created AAA group from **Available Servers** to **Assigned Servers**.
8. Click **Apply to Device**.

Configure a AAA Group configuration (CLI)

This topic describes how to configure a AAA Group configuration using the CLI.

Configure a AAA group configuration using the CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure the RADIUS server group name and server group configuration.

   Example

   ```
   Device(config)# aaa group server radius MY-SERVER-GROUP
   ```
3. Re-format the delimiter of the username attribute.

Example

```
Device(config-sg-radius)# mac-delimiter {colon | hyphen | none | single-hyphen}
```

The options are:

a. **colon**: Sets the delimiter to colon (for example, xx:xx:xx:xx:xx:xx).

b. **hyphen**: Sets the delimiter to hyphen (for example, xxxxxxxxxxxx).

c. **none**: Sets the delimiter to none (for example, xx-xx-xx-xx-xx-xx).

d. **single-hyphen**: Sets the delimiter to single-hyphen (for example, xxxxxx-xxxxxx).

> **Note**
>
> The default delimiter is **none**. If nothing is configured, **none** is set to the username, that is, the MAC address goes without any delimiter to the respective RADIUS server.

4. Set the MAC address as the password.

Example

```
Device(config-sg-radius)#subscriber mac-filtering security-mode {mac | none
| shared secret}
```

The options are:

a. **mac**: The delimiter format of the MAC address in the RADIUS user password attribute is same as that of the MAC address string in the RADIUS username attribute.

b. **none**: MAC address string without any delimiter is sent as RADIUS user password.

c. **shared-secret**: The shared-secret option is not supported for the AP join use case.

> **Note**
>
> The default delimiter is **none**. If nothing is configured, the user password attribute is sent as the MAC address without delimiter. If **mac** is configured as the delimiter, then the delimiter format of the username attribute is applied to the MAC address string of the user password attribute.

5. Associate the RADIUS server to the server group.

Example

```
Device(config-sg-radius)# server name ISE
```

6. Configure the authorization method list with the named RADIUS server group.

Example

```
Device(config)# aaa authorization credential-download MY-METHOD-LIST group
MY-SERVER-GROUP
```

7. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-sg-radius)# end
```

Create a AAA Group Server configuration (GUI)

Create a AAA Group My Server configuration using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **AAA Method List** > **Authorization**.
2. Click the **Add** button.
   The **Quick Setup: AAA Authorization** dialog box is displayed.
3. Enter a name in the **Method List Name** field.
4. Select **Type** as **Credential-Download** from the drop-down list.
5. Select **Group Type** as **Group** from the drop-down list.
6. Add the newly created AAA group from **Available Server Groups** to **Assigned Server Groups**.
7. Click **Apply to Device**.

Create a AAA Group Method List configuration (GUI)

This topic describes how to create a AAA Group Method List configuration using the GUI.

Create a AAA group method Method List configuration using the GUI.

Procedure

1. Choose **Configuration** > **Security** > **AAA** > **AAA Advanced** > **AP Policy**.
2. Use the toggle button to enable **Authorize APs against MAC** and configure **ap auth-list authorize-mac** on your controller.
3. Select AP-MAC-Method for **Authorization Method List** from the drop-down list to configure **ap auth-list method-list MY-METHOD-LIST** on your controller.
4. Click **Apply**.

Configure AP MAC authorization (CLI)

This topic describes how to configure AP MAC authorization using the CLI.

Configure AP MAC authorization using the CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure AP authorization list.

   Example

   ```
   Device(config)# ap auth-list {authorize-mac | method-list method-list-name}
   ```

   The options are:

   - **authorize-mac**: Sets AP authorization policy with MAC.
   - **method-list**: Sets AP authorization method-list.

3. Enter the method-list to be used for AP MAC authorization.

   Example

   ```
   Device(config)# ap auth-list method-list MY-METHOD-LIST mac
   ```

4. Save the configuration and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-auth-list)# exit
   ```

Verify MAC authorization details

Verify the AP authentication list.

Verify AP authentication list

To verify if the controller has enabled the AP authentication list, run the **show ap auth-list** command.

```
Device# show ap auth-list

Authorize APs against MAC : Disabled
Authorize APs against Serial Num : Enabled
Authorization Method List : <auth-list-name>
```

Verify AP status summary

To verify the status summary of all Cisco lightweight APs attached to the device, run the **show ap summary** command.

```
Device# show ap summary

Number of APs: 1
```

```
Global AP User Name: Cisco
Global AP Dot1x User Name: Not configured

```

24 AP Joining

Topics:

- Failover priority for APs
- AP Plug-n-Play
- AP fallback to controllers using AP priming profile

Failover priority for APs

Explains how failover priorities for access points determine which devices maintain connectivity when controller capacity is limited.

A failover priority for APs is a configuration setting that:

- assigns priority levels to APs for controller association
- determines which APs will be favored when controller capacity is limited, and
- allows administrators to ensure high-priority devices maintain connectivity during failover scenarios

Each controller supports a set number of AP connections. If you deploy multiple controllers on the network and one fails, your APs can automatically connect to another available controller.

Guidelines to configure AP failover priority

Use these guidelines to configure AP failover priority:

- Failover priority does not impact normal wireless operation. It only applies when AP connection requests exceed the controller's available capacity.
- The system checks AP priority as each AP connects. When capacity is full, or the primary controller fails, APs connect to the secondary controller.
- Enable failover priority and set priority levels for APs that need them.
- By default, all APs have priority level one (lowest). Assign higher levels only where needed.

Set AP priority (GUI)

Set AP priority using GUI.

Assign a failover priority to an AP to ensure high availability in the event of a controller failure.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the Access Point.
3. In the **Edit AP** dialog box, go to the **High Availability** tab.
4. Select the priority from the **AP failover priority** drop-down list.
5. Click **Update and Apply to Device**.

Set AP priority (CLI)

Set AP priority using commands.

Assign a priority level to an AP to determine the order in which APs connect and operate using commands.

> **Note**
>
> Priority of APs ranges from one to four, with four being the highest.

Procedure

1. Specify the priority of an AP.

   Example

   ```
   Device# ap name ap-name AP44d3.ca52.48b5 priority 1
   ```

2. Display common information for all APs.

   Example

   ```
   Device# show ap config general
   ```

3. Display the configuration of a particular AP.

   Example

   ```
   Device# show ap name ap-name AP44d3.ca52.48b5 config general
   ```

AP Plug-n-Play

Explains the capabilities and configuration options that AP Plug-n-Play features provide for deploying access points.

AP Plug-n-Play (PnP) features are configuration capabilities that

- deliver staging parameters to APs before they join a controller
- allow runtime configuration transfer when an AP joins the controller using the staging configuration, and
- enable the PnP server to provide all tag-related information. You provide this as part of the preconfigured information to the AP and then to the controller.

You can upload configuration to the PNP server in either **TXT** or **JSON** format. You can also add the AP details. The AP details are mapped to the information in the **TXT** or **JSON** configuration file. While provisioning the AP from the PnP server, the AP acquires these configuration details. Based on the configuration details, the AP joins the corresponding controller with the tag information.

Provision AP from PnP server

Provision AP from PnP server.

You can provision AP from PnP Server in either ways:

- Configure DHCP server or switch with **Option 43**. For example, you can refer to the code sample:

```
ip dhcp pool vlan10
network 9.10.10.0 255.255.255.0
default-router 9.10.10.1
option 43 ascii 5A1D;B2;K4;I9.10.60.5;J80
```

- Configure DHCP server with DNS with **domain-name dns.com**. For example, you can refer to the code sample:

```
ip dhcp pool vlan10
network 9.10.10.0 255.255.255.0
default-router 9.10.10.1
dns-server 9.8.65.5
domain-name dns.com
```

Verify AP tag configuration

Verify AP tag configuration.

The example shows how to verify the AP tag configuration:

```
Device# show ap tag summary
Number of APs: 5

AP Name                  AP Mac           Site Tag Name           Policy Tag
Name         RF Tag Name             Misconfigured    Tag Source

-------------------------------------------------------------------------------------------------

APd42c.4482.6102         d42c.4482.6102   default-site-tag
default-policy-tag       default-rf-tag          No               Default

AP00c1.64d8.6af0         00c1.64d8.6af0   named-site-tag
named-policy-tag         named-rf-tag            No               AP
```

Note

The tag source in the second row originates from the PNP server.

AP fallback to controllers using AP priming profile

Explains how AP priming profiles centralize controller assignments and automate AP fallback behavior in large wireless networks.

An AP priming profile is a controller configuration that

- defines primary, secondary, and tertiary controller assignments for APs
- enables centralized assignment of controllers for groups of APs or individual devices, and

- automates fallback and reconnection behavior when APs lose connection with their assigned controllers.

In large networks, configuring AP priming for primary, secondary, and tertiary controllers on each AP is difficult. Simplify AP priming by using the AP fallback to controllers using AP priming profile feature. Use profiles defined in the controller to assign controllers to APs.

To configure primary, secondary, and tertiary controllers, use the AP priming profile under the AP filter profile. Apply it to a group of APs matching regular expressions or to an individual AP by using its Ethernet MAC address. When the AP joins the controller, the controller sends the AP priming configuration to the AP if priming override is enabled.

Note

When the controller sends a priming profile to the AP, the AP disconnects from the current controller and joins the controller in the priming profile. A CAPWAP restart or device reboot is not required.

Feature History

This table provides release and related information for the feature explained in this module.

Table 29: Feature History for AP Fallback to controllers using AP priming profile

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.2	AP Fallback to controllers using AP priming profile	This feature helps to configure primary, secondary, and tertiary controllers for a group of APs matching regular expression or for an individual AP using priming profiles.

AP controller selection and onboarding behavior

Review these points to choose the best AP controller and onboard APs effectively.

- Ensure APs always reconnect to their primary controller as soon as it becomes available; APs automatically disassociate from backup controllers when the primary controller is online. The AP does not switch to secondary controllers even if they are available.
- Configure primary, secondary, and tertiary controllers so that an AP connects to the tertiary controller only if both the primary and secondary controllers are unresponsive. If only the secondary controller recovers while the primary is still down, keep the AP connected to the tertiary controller until the primary is available. If the tertiary controller fails and the primary is still down, switch the AP to the available secondary controller.
- Do not use the AP Onboarding VLAN for client onboarding, as it results in address overlap errors.
- AP scale limits specify the maximum number of APs supported once they have joined. This limit does not determine how many APs can join at the same time or guarantee a particular recovery time. When an N+1 failover or controller recovery affects many APs, they may rejoin in several waves. The time required for all APs to rejoin depends on the number of reconnecting APs and controller and network conditions.

Restrictions for AP fallback to controllers using AP priming profile

AP fallback to controllers using AP priming profile restrictions.

- You must create a filter to complete the AP priming process. Without a filter, the system cannot determine which APs to apply the priority to, and the priming operation will not proceed.
- Rolling AP upgrade does not work if priming override is enabled.
- The maximum number of priming profiles allowed is 128.
- Each profile can be up to 32 ASCII characters long.

Configure AP priming profile (CLI)

Configure AP priming profile using commands.

Set up an AP priming profile to specify primary, secondary, and tertiary controllers for AP fallback.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the profile to prime APs.

   Example

   ```
   Device(config)# wireless profile ap priming profile-name Prime-FX
   ```

3. Configure the name and IP address of the primary controller for AP fallback.

   Example

   ```
   Device(config-priming)# primary controller-name aaaa ip-address 209.165.201.2
   ```

4. Configure name and IP address of the secondary controller for AP fallback.

   Example

   ```
   Device(config-priming)# secondary controller-name bbbb ip-address 209.165.201.3
   ```

5. Configure name and IP address of the tertiary controller for AP fallback.

   Example

   ```
   Device(config-priming)# tertiary controller-name bbbb ip-address 209.165.201.4
   ```

6. Send the priming details to the AP.

   Example

   ```
   Device(config-priming)# priming-override
   ```

Priming override is disabled by default. If priming override is disabled, the AP does not receive the information stored in the AP priming profile.

> **Note**
>
> N+1 upgrade may not work as expected when priming override is enabled. Before using N+1 upgrade, ensure that priming override is disabled using the **no priming-override** command.

Configure AP priming using filters (CLI)

Configure AP priming using filters using commands.

Configure AP priming filters and assign profiles using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP filter and sets the type as priming.

   Example

   ```
   Device(config)# ap filter name filter-name test-filter type priming
   ```

   Set the filter type to priming. The default filter type is tag.

   > **Note**
   >
   > To modify the filter type, delete the existing filter and create a new one with the desired type. Delete a filter by using the **no ap filter name** command.

3. Configure the AP name regular expression match.

   Example

   ```
   Device(config-ap-pr-filter)# ap name-regex reg-ex BGL18
   ```

4. Map the priming profile to the filter.

Example

```
Device(config-ap-pr-filter)# profile profile-name Prime-FX
```

5. Return to the global configuration.

Example

```
Device(config-ap-pr-filter)# exit
```

6. Configure priority for a named AP filter.

Example

```
Device(config)# ap filter priority priority 12 filter-name test-filter
```

Configure multiple AP priming profiles, each with a unique priority level. This allows you to set different priority levels for each AP priming profile.

Configure Per-AP priming (CLI)

Configure Per-AP priming using commands.

Assign a priming profile to a specific AP using the commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the AP profile configuration mode.

Example

```
Device(config)# ap mac-address 00:00:5e:00:53:af
```

3. Map a priming profile to an AP.

Example

```
Device(config-ap-tag)# priming profile-name Prime-FX
```

Verify priming filter configuration

Verify priming filter configuration.

To view the list of all the priming filters, use the command:

```
Device# show ap filters all type priming

Filter Name                        regex                                  Priming
 profile
-------------------------------------------------------------------------------------
FLR1                                *AP-FLOOR-1*
AP-PRIMING-1
FLR2                                *AP-FLOOR-2*
AP-PRIMING-2
```

To view the list of all the active priming filters, use the command:

```
Device# show ap filters active type priming

Priority   Filter Name              regex                                 Priming
profile
-------------------------------------------------------------------------------------

 0          FLR2                    *AP-FLOOR-2*
AP-PRIMING-2

 1          FLR1                    *AP-FLOOR-1*
AP-PRIMING-1
```

To view the summary of the priming profiles, use the command:

```
Device# show wireless profile ap priming summary

Number of AP Priming Profiles: 2
Priming profile
-------------------
AP-PRIMING-1
AP-PRIMING-2
```

To view the details of the priming profiles, use the command:

```
Device# show wireless profile ap priming all

Profile Name  Primary Controller Name  Primary Controller IP  Secondary
Controller Name  Secondary Controller IP  Tertiary Controller Name  Tertiary
Controller IP  Override
-------------------------------------------------------------------------------------
AP-PRIMING-1  BGL18-wlc               209.165.201.1          BGL17-wlc
            209.165.201.2                                      0.0.0.0
          Disabled
AP-PRIMING-2  BGL18-wlc               209.165.201.2          BGL17-wlc
            209.165.201.2            BGL12-wlc                 209.165.201.3
          Disabled
```

To view the priming information for each AP, use the command:

```
Device# show ap name ap1 config general | sec Priming

Priming Profile                  : AP-PRIMING-1
Priming Override                 : Disabled
Priming Source                   : MAC/FILTER/NONE
Filter Name                      : FLR1
```

25 AP Crash File Upload

Topics:

- AP crash files

AP crash files

Introduces AP crash file upload, detailing foundational concepts, outlines restrictions for secure and effective operation, and provides instructions for configuring AP crash file upload using CLI commands.

A crash file is a diagnostic file that

- is created when an AP experiences an unexpected reboot
- contains information about the state of the AP at the time of the crash, and
- is stored in the local flash memory of the AP for retrieval.

AP crash files provide data that is essential for diagnosing the causes of unexpected reboots in access points. This data aids in troubleshooting and maintenance.

> **Note**
>
> An unexpected reboot of the AP is considered a crash.

Process crash details

When a process crashes, the device collects various types of data. and compiles it into a single, compressed archive for analysis. This archive includes:

- Full process core
- Trace logs
- Cisco IOS syslogs (not guaranteed in case of nonactive crashes)
- System process information
- Bootup logs
- Reload logs
- Certain types of proc information

Except for the full core and tracelogs, everything else is a text file. This consolidated information provides a snapshot of the AP's state, which can be used for further diagnosis.

Restrictions for AP crash file upload

- Reports are not generated by the system in case of a reload.

Configure AP crash file upload process (CLI)

Set up and configure an access point to collect and upload crash files for diagnostics.

This involves configuring multiple data collection commands and ensuring files are available for troubleshooting access point failures.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Collect AP crash information.

   Example

   ```
   Device# ap name ap-name crash-file get-crash-data
   ```

   The crash file is uploaded automatically after the AP reloads to the ready state. As a result, this command does not have to be manually executed.

3. Collect the AP core dump file for slot 0 or slot 1.

   Example

   ```
   Device# ap name ap-name crash-file get-radio-core-dump slot {0 | 1}
   ```

4. Upload the AP crash coredump file to the given TFTP location.

   Example

   ```
   Device# ap name ap-name core-dump tftp-ip crash-file uncompress
   ```

5. Display your AP crash file and the radio crash file.
6. Display the crash file in bootflash with .crash extension.

   Example

   ```
   Device# dir bootflash
   ```

The AP crash files and core dumps are collected and available in specified locations for troubleshooting.

26 LED States for Access Points

Topics:

- LED states for APs

LED states for APs

Introduces LED state features for access points, guides configuration using GUI and CLI, details AP profile settings, and provides verification commands for monitoring LED status and ensuring proper operation.

A LED state for access points is a configuration that

- allows the identification of specific access points in a LAN network
- can be configured globally or for individual APs, and
- prioritizes global configurations over individual AP settings.

Note

When disabling the LED on an AP, the LED state that is controlled by the AP-Join profile.

To maintain the LED in a disabled state, it is recommended to create a separate AP-Join profile and Site Tag specifically for APs with the LED disabled.

Note

For APs that have Ethernet LEDs in addition to the main system LED, the Ethernet LEDs are enabled or disabled (switched ON or OFF) as per the system LED. For example, if the system LED is ON, the Ethernet LED will also be ON.

Configure the LED State on APs (GUI)

Configure LED state in access points using GUI.

Configure the LED state on access points to optimize visibility and performance using the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click an AP from the AP list.
   The **Edit AP** window is displayed.
3. In the **General** tab, under the General section, go to **LED Settings**.
   a) Click the box adjacent to the **LED State** field to enable or disable the LED state.
   b) From the **LED Brightness Level** drop-down list, choose a value from 1 to 8.
4. Under the **Flash Settings** section, perform the following steps:
   a) Click the box adjacent to the **Flash State** field to enable or disable the flash state.
   When the flash state is enabled, the current status of the flash and the flash duration fields are displayed.
   b) From the **Flash Duration** drop-down list, choose either **Always ON** or **Timed**.
   If you choose the **Timed** option, the **Time Duration** field is displayed.
   c) In the **Time Duration** field, specify the flash duration time, in seconds. The default value is one second. The range is between 1 and 3600 seconds.

5. Click **Update & Apply to Device**.

The LED state and related settings on the access points are configured according to your selections, enhancing network device visibility or conserving energy.

Configure LED state for APs (CLI)

Configure LED State for APs in the global configuration mode using commands.

Configure the LED state for APs in the global configuration mode using commands.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password if prompted.

2. Enable the LED state for APs, globally.

   Example

   ```
   Device# ap name Cisco-AP-name led
   ```

3. Configure the starting and the stopping of the AP LED flash.

   Example

   ```
   Device# ap name Cisco-AP-name led flash start duration 20
   ```

   ```
   Device# ap name Cisco-AP-name led flash stop
   ```

   The valid start duration range is between zero and 3600 seconds.

4. Configure the LED brightness level.

   Example

   ```
   Device# ap name Cisco-AP-name led-brightness-level 4
   ```

   The brightness value ranges from 1 to 8.

The LED state is successfully configured with adjusted brightness and flash settings according to commands executed.

Configure LED state in the AP profile

Configure LED state in the AP profile using commands.

The task enables the LED state for all APs, ensuring active visual indicators across the network.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the AP profile configuration mode.

   Example

   ```
   Device(config)#ap profile default-ap-profile
   ```

3. Enable the LED-state for all APs.

   Example

   ```
   Device(config-ap-profile)# led
   ```

Verify that the LED status is visible on the access point, confirming successful configuration.

Verify LED state for APs

Verify LED state for APs.

To verify the LED state of the APs, use this command

```
Device# show ap name AXXX-APXXXX.bdXX.f2XX config general
Cisco AP Name : AXXX-APXXXX.bdXX.f2XX
=====================================================
Cisco AP Identifier : 0cXX.bdXX.65XX
Country Code : Multiple Countries : FR,IN,US
Regulatory Domain Allowed by Country : 802.11bg:-AE 802.11a:-ABDEN
AP Country Code : US - United States
AP Regulatory Domain
802.11bg : -A
802.11a : -B
.
.
.
CAPWAP Preferred mode : IPv4
CAPWAP UDP-Lite : Not Configured

.
```

27 AP Support Bundle

Topics:

- AP support bundle

AP support bundle

Introduces Access Point Support Bundle functionality, guiding users through export processes using GUI and CLI methods, and detailing procedures for monitoring the status of support bundle exports for effective wireless issue analysis.

An AP support bundle is a data package that

- contains core files, crash files, show run configuration, configuration commands, message logs, and trap logs, and
- is supported only on Cisco Wave2 APs and Cisco Catalyst APs.

Feature history for AP support bundle
Table 30: Feature history for secure data wipe

Release	Feature	Feature Information
Cisco IOS XE 17.3.1	AP support bundle	You can now retrieve the support bundle information of an AP and export it to the controller or an external server.

The AP Support Bundle feature provides comprehensive diagnostic information for troubleshooting and configuring the AP.

Retrieving support bundle information

Retrieve the support bundle information of your AP and export it to the controller or an external server.

Note

The destination file path for a Cisco Catalyst 9800 controller-initiated SCP copy of an AP's support bundle must be a pre-existing folder name.

```
ap name APNAME export support-bundle mode scp target ip-address 10.11.12.13
 path /
ap name APNAME export support-bundle mode scp target ip-address 10.11.12.13
 path flash:
ap name APNAME export support-bundle mode scp target ip-address 10.11.12.13
 path /BUNDLE
```

Export an AP support bundle (GUI)

Export an access point support bundle using GUI.

You can export an AP support bundle using GUI for analysis or backup.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the corresponding AP name.

The **Edit AP** window is displayed.

3. Click the **Support Bundle** tab.
4. From the **Destination** drop-down list, choose one of the following:
   - **This Device**: If you choose this, enter the values for the **Server IP**, **Destination File Path**, **Controller Username**, and **Password** fields.

     When you choose **This Device**, a bundle is sent through Secure Copy (SCP) to the controller (if you have configured the **ip scp server enable** command globally on the controller). You can easily retrieve the bundle later from your browser, using the controller file manager.
   - **External Server**: If you choose this, from the **Transfer Mode** drop-down list, choose either **scp** or **tftp**.

     If you choose the **scp** transfer mode, enter the values for the **Server IP**, **Destination File Path**, **Controller Username**, and **Password** fields.

     If you choose the **tftp** transfer mode, enter the values for the **Server IP**, and **Destination File Path** fields.

   Information about the **Last Export Status**, such as **State**, **Transfer Mode**, **Server IP**, **File Path**, and **Time of Export**, is displayed on the right-hand side of the window.
5. Click **Start Transfer** to initiate the export.

Once you complete the transfer, the AP support bundle is ready at your chosen destination for analysis or backup.

Export an AP support bundle (CLI)

Export an AP support bundle using commands.

This task guides you to export a support bundle from an access point using CLI commands. This helps in troubleshooting and support.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.
2. Export the AP support bundle through the SCP or TFTP transfer modes.

   Example

   ```
   Device> ap name Cisco-AP-name export support-bundle mode scp target ip-address
    10.1.1.1 path file-path
   ```

   If you select the **scp**, you will be prompted to provide your username and password.

   For **tftp**, username and password are not required.

The AP support bundle is successfully exported to the specified file path using the selected transfer mode.

Monitor the status of support bundle export

Monitor the status of support bundle export.

To monitor the status of a support bundle export, run this command:

```
Device# show ap support-bundle summary
AP Name    Server-IP   Status        Last Successful Time      Path File-name
──────────────────────────────────────────────────────────────────────────────
AP_28XXX   10.1.1.10   Copy Success  04/24/2020 07:27:38 UTC
AP_28XXX_support.17.4.0.2.2020.07XXXX.tgz
```

28 Access Point Memory Information

Topics:

- Access point memory information

Access point memory information

Introduces key concepts of access point memory, describing the types, organization, and roles of memory within APs, and provides verification steps to review and assess AP memory information.

Access point memory information is a feature that

- allows viewing the memory type of an AP
- provides details about the CPU type of the AP, and
- displays the memory size per AP after single sign-on authentication.

This feature enables APs to report hardware specifications to the controller during the join phase. This enhancing network visibility and aids hardware-related troubleshooting.

Verify AP memory information

Verify access point memory information.

To verify the memory information of a specified AP, including the CPU type, memory type and memory size, use thia command:

```
Device# show ap name AP-NAME config general
Cisco AP Name    : AP-NAME
================================================
Cisco AP Identifier                              : 00XX.f1XX.e0XX
Country Code                                    : Multiple Countries : FR,IN,US
Regulatory Domain Allowed by Country            : 802.11bg:-AE   802.11a:-ABDEN
AP Country Code                                  : US  - United States
AP Regulatory Domain
  802.11bg                                       : -A
  802.11a                                        : -B
.
.
.
CPU Type                                         : ARMv7 Processor rev 1 (v7l)
Memory Type                                      : DDR4
Memory Size                                      : 1028096 KB
.
.
.
```

29 Access Point Tag Persistency

Topics:

- AP tag persistency

AP tag persistency

Introduces AP tag persistency concepts, outlines recommendations for AP rejoin after enabling tag persistency, details requirements for tag consistency across controllers, describes redundancy scenarios, and provides step-by-step configuration and verification procedures in both GUI and CLI environments.

AP tag persistency is a configuration feature that

- allows mapped tags to be saved locally on APs
- enables APs to retain tag configurations when moving between controllers, and
- removes the need for reapplying tags individually on each AP.

Feature history for AP tag persistency
Table 31: Feature history for secure data wipe

Release	Feature	Feature Information
Cisco IOS XE 17.6.1	AP tag persistency	Global tag persistency configuration on the controller that automatically write tags on the APs.

Supporting reference information

- The feature is disabled by default and must be explicitly enabled on the controller.
- When enabled, any AP that joins a controller stores the mapped tags locally.

Recommendation: Rejoin APs after enabling tag persistency

Recommendation for rejoining APs after enabling tag persistency.

After enabling AP tag persistency on a controller, ensure that all existing APs rejoin the controller for the configuration to take effect.

Requirement: Match tags across controllers

To retain tag configuration across different controllers:

- Ensure that the policy tag, site tag, and RF tag exist on all controllers an AP might connect to.
- If all three tags do not exist on a new controller, the AP will use default tags.
- Even if one or two tags exist, tag persistency can still apply using available tags.

Tag persistency for redundancy scenarios

Tag persistency helps in N+1 redundancy scenarios by ensuring that an AP retains its previously assigned tags when moving between controllers. This process assumes that the tags (policy, site, RF) exist on the secondary controller. If all required tags do not exist, the AP reverts to default tags. For more information, see "*New Configuration Model*" chapter in *Cisco Catalyst 9800 Series Wireless Controller Software Configuration Guide*.

Configure access point tag persistency (GUI)

Configure access point tag persistency using GUI.

The purpose of this task is to enable tag persistency on APs. It allows them to retain their tag mapping information without requiring individual configuration after reconnection.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click the **AP** tab.
3. In the **Tag Source** tab, check the **Enable AP Tag Persistency** check box to configure AP Tag persistency globally.

   When APs join a controller with the tag persistency enabled, the mapped tags are saved on the AP without having to write the tag configurations on each AP individually.
4. Click **Apply to Device**.

The AP tag persistency is enabled, allowing access points to retain their tag configurations even after disconnections.

Save tags on an access point (GUI)

Save tags on an AP using the GUI.

This task guides you on how to save tags, including policy, site, and RF tags, on an access point using the graphical user interface (GUI). Saving tags ensures the access point remembers its configuration across different controllers.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click an AP from the list.
   The **Edit AP** page is displayed.
3. Click the **General** tab.
4. In the **Tags** section, specify the appropriate policy, site, and RF tags that you created in the **Configuration** > **Tags & Profiles** > **Tags** page.
5. From the **Policy** drop-down list, select a value.
6. From the **Site** drop-down list, select a value.
7. From the **RF** drop-down list, select a value.
8. Check the **Write Tag Config to AP** check box to push the tags to the AP so that the AP can save and remember this information even when the AP is moved from one controller to another.
9. Click **Update & Apply to Device**.

The AP saves the specified tags and configurations, allowing seamless operation even if the AP is transferred between controllers.

Delete saved tags on an access point (GUI)

Delete saved tags on an access point.

The purpose of this task is to guide you to delete saved tags on an access point through the GUI.

Use these steps to delete saved tags on an access point:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click an AP from the list of APs.

   The **Edit AP** window is displayed.
3. In the **Edit AP** window, choose the **Advanced** tab.
4. In the **Set to Factory Default** section, check the **Clear Resolved Tag Config** check box to clear the saved tags on an AP.
5. Click **Update & Apply to Device**.

The access point is updated and all saved tags are cleared.

Configure AP tag persistency (CLI)

Configure access point tag persistency using commands.

Configure AP tag persistency to ensure APs maintain their assigned tags when connecting to different controllers, which aids in redundancy scenarios.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure AP tag persistency

   Example

   ```
   Device(config)# ap tag persistency enable
   ```
3. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

After completing these steps, the AP tag persistency feature will be enabled on the controller, ensuring APs keep their tag assignments when moving to different controllers.

Verify AP tag persistency

Verify access point tag persistency.

To verify AP tag persistency in the primary controller, use this command:

```
Device# show ap tag summary
Number of APs: 1

AP Name         AP Mac           Site Tag Name         Policy Tag Name
 RF Tag Name            Misconfigured    Tag Source
-------------------------------------------------------------------------------
Cisco01_AP      xxxx.xxxx.xxxx   default-site-tag      OpenRoaming
 default-rf-tag         No               Static
```

If the Tag Source displays **Static** or **Filter**, it means that the AP tag mappings were configured on the primary controller. If the source displays **Default**, it means that the AP received the default tags when joining the controller.

To verify the AP tag persistency in the secondary controller, use this command:

```
Device# show ap tag summary
Number of APs: 1

AP Name       AP Mac           Site Tag Name        Policy Tag Name     RF Tag
 Name       Misconfigured   Tag Source
-------------------------------------------------------------------------------
Cisco01_AP   xxxx.xxxx.xxxx    default-site-tag     OpenRoaming
default-rf-tag     No              AP
```

If the Tag Source displays **AP**, it means that the policy tag, site tag, and RF tag match what was configured on the primary controller, indicating that the AP tags have persisted across controllers.

30 AP Power Save

Topics:

- Access point power save

Access point power save

AIntroduces access point power save capabilities, outlines configuration options and supported features across Cisco IOS XE releases, and details enhancements for energy efficiency, flexible policies, and supported access point models.

Access point power save is a power management capability that

- enables APs to reduce energy consumption during periods of inactivity
- supports flexible scheduling and policies for low-power operation, and
- helps optimize network efficiency without compromising performance.

This feature is critical in modern enterprise environments where reducing operational costs and improving environmental impact are priorities. Cisco APs offer multiple configurations to enable power save modes, such as calendar-based scheduling and client threshold triggers

Feature history for access point power save
Table 32: Feature History

Release	Feature Information
Cisco IOS XE 17.18.1	Multi-Link Operation (MLO) is now supported even when radios are operating in low-power mode. This enhancement ensures seamless multi-link operations under constrained power conditions, providing improved flexibility and efficiency for network operations. This feature is supported on the following access points only: • Cisco Wireless 9178 Series Access Points. • Cisco Wireless 9176 Series Access Points.
Cisco IOS XE 17.13.1	AP Power Distribution support in Cisco Catalyst 9124 Series APs.
Cisco IOS XE Dublin 17.10.1	These features are supported: • Radio spatial streams • Flexible Power over Ethernet (PoE) profiles
Cisco IOS XE Cupertino 17.9.1	Feature support for the following APs: • Cisco Catalyst 9164 Series Access Points • Cisco Catalyst 9166 Series Access Points
Cisco IOS XE Cupertino 17.8.1	This feature allows a network administrator to force APs to operate in low-power mode to reduce power consumption.

For more information about the APs that support the AP Power Save feature, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html.

Tips for AP power save configuration

- Use spatial stream adjustments to optimize power: From Cisco IOS-XE Cupertino 17.10.1 onwards, you can shut down AP radios or lower the radio spatial streams, to reduce usage of power. You can enforce radio speed by configuring the number of spatial streams on the radios. The combinations for radio spatial stream policies are: 1X1, 2X2, 3X3 (only for Cisco Catalyst 9130 Series Access Points), 4X4, and 8X8.
- Use calendar profiles for predictable power reduction: You can define regular sleep intervals using calendar profiles to maximize energy savings without disrupting business hours.

Requirements for AP power save configuration

- Enable RLAN port before using PoE-out: PoE-out functionality requires the RLAN port to be enabled. Ensure this is configured before applying any PoE-out power profile.

Best practice for AP power save configuration

- Setting client thresholds: Set the client wakeup threshold to a realistic minimum (e.g. 3–5 clients) to avoid unnecessary power cycling and improve user experience.

Warnings for AP power save configuration

- Do not disable uplink interfaces: Do not configure the AP uplink Ethernet port for shutdown in any power profile. The uplink is required for controller communication and management

AP power policies

Access point power policy details.

Access point power policies are a set of policies that

- define power budget utilization for an AP
- allow management of different interfaces on an AP, and
- support different modes for Cisco Catalyst 9124 APs under insufficient power conditions.

These policies help adapt AP behavior to different input power scenarios (for example, 802.3af, 802.3at, 802.3bt, DC) and ensure reliable operation even under limited power supply.

Additional reference information

- Cisco Catalyst 9124 AXI Series APs and Cisco Catalyst 9124D Series APs support up to two radio interfaces (single 5 GHz).
- Cisco Catalyst 9124 AXE APs support up to three (dual 5 GHz) radio interfaces.
- Operation modes under 8802.3, PoE, and 30 W insufficent power conditions conditions include dual or tri-radio modes.

Use case for AP power policy

These are the use cases of an AP power policy:

- Define a power policy for available power inputs, such as 802.3af, 802.3at, 802.3bt, and DC power.
- Predetermine AP operations for non-802.3bt power situations with tri-radio or quad-radio APs.

Power-save modes

Power-Save Mode details.

A power-save mode is a wireless AP power management feature that

- enables the AP to switch to a low-power state when no clients are associated
- reduces energy consumption by minimizing AP activity during off-peak hours, and
- allows organizations to improve energy efficiency and support environmentally conscious initiatives.

Additional reference information

When power-save mode is enabled, the AP can "fall asleep" after hours in workspaces or other deployment scenarios where client activity is absent, thereby saving power throughout the night.

These are the advantages of power save mode:

- Increases the energy saving per AP: By reducing AP functions during off-peak hours, power-save mode can save an additional 20 percent in energy costs compared to the regular idle mode.
- Enables environmentally conscious purchases: Large enterprises and companies often track environmental performance as a key index. Power-save mode helps support these goals by enabling centralized monitoring of energy efficiency by energy teams.

Use case for power save mode

During after hours in a workspace, when no wireless clients are connected, the AP enters power-save mode and reduces its power usage automatically for the duration of the night.

Release-specific feature support

- In Cisco IOS XE Release 17.15.x, Multi-Link Operation (MLO) is not supported if any radio operates in low power mode.
- However, from Cisco IOS XE Release 17.18.1 onwards, MLO support is enabled even when any of the radios are in low power mode. This feature is applicable on Cisco Wireless 9178 Series Access Points and Cisco Wireless 9176 Series Access Points only.

PoE profiles

PoE Profile details.

A PoE profile is a power allocation framework that

- facilitates negotiation and adaptation of power levels based on AP requirements
- comprises fixed and flexible options for interface configuration, and
- supports policy-based profiles customized for both normal and power-saving operational modes.

Types of PoE profiles

- Fixed PoE profiles: predefined settings per model, typically for full-power mode.
  - Fixed PoE Profiles enable APs to negotiate the power required from the switches they are connected to. The power needed can vary between different AP models.
  - If an AP does not receive the power it requests, it operates within the power budget. It can cause certain interfaces to function under degraded conditions. For instance, radios might operate at 2SS instead of their full 4SS capability.

    - These profiles are used when APs are in normal operation mode (nonpower-save mode). During power-save mode, the configured PoE power policies are applied instead.

- PoE Power Policy: schedule-based profiles for different times of day.
    - PoE Power Policies allow for the configuration of interfaces to specific speeds or settings according to a schedule.
    - These policies can push a defined profile to APs based on timing or calendar settings, such as turning off all but the 2.4-GHz radio and the multigigabit Ethernet at 100 MB at specific times, for example, from 7 p.m. to 7 a.m. on a group of APs located on a second floor.

- Flexible PoE Profiles: customizable profiles for interface-level power control.
    - Flexible PoE Profiles allow you to configure different interfaces with specific parameter values and states, instead of fixed profile rules.
    - In case an AP does not obtain the necessary power, it operates under the power budget, following the guidelines of the flexible PoE profile.

Additional Reference Information

- Operational parameters for each AP interface may be modified based on the hardware specifications, as detailed in the accompanying tables.

AP power draw specifications

AP power draw specifications.

This section provides detailed specifications on the power draw requirements for various AP models to enable accurate planning and deployment in network setups.

Table 33: AP Power Draw Specifications

AP	Power Draw Specification
Cisco Wireless 9172 Series Access Points	See the *Input power requirements* in the *Product specifications* section of Cisco Wireless 9172 Series Access Points Data Sheet
Cisco Wireless 9176 Series Access Points	See the *Input power requirements* in the *Product specifications* section of Cisco Wireless 9176 Series Access Points Data Sheet
Cisco Wireless 9178 Series Access Points	See the *Input power requirements* in the *Power over Ethernet* section of Cisco Wireless 9178 Series Access Points Data Sheet

Client wakeup threshold

Wakeup threshold for access point power save mode.

A wakeup threshold is a power management feature in access points that

- defines the minimum number of client associations required to exit power-save mode
- is used to re-enable radios and interfaces when demand returns, and
- helps optimize energy efficiency in low-use environments.

Load-based wakeup threshold for AP power save mode

When the AP applies a power profile associated with an active calendar, the number of connected clients is compared to the wakeup threshold:

- If the number of connected clients reaches or exceeds the wakeup threshold, the AP exits power save mode and becomes active to ensure adequate performance.
- If the number of connected clients is less than the wakeup threshold, the AP either shuts down the interface or reduces interface speed to save power, maintaining energy efficiency.

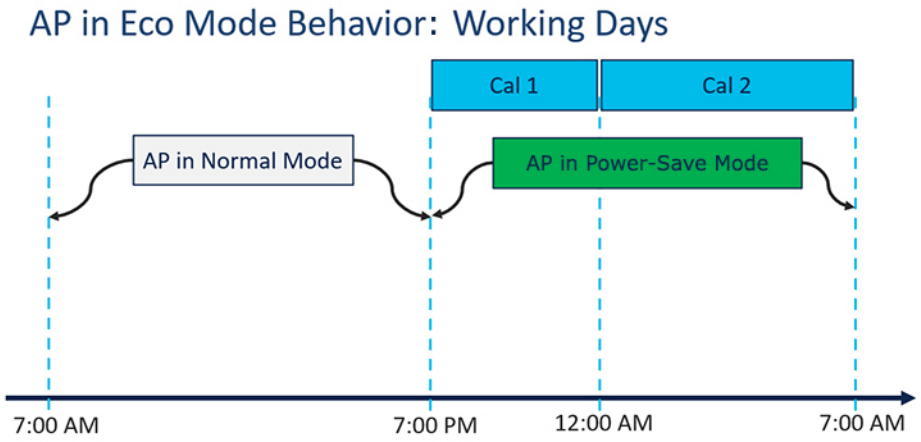
This feature dynamically adjusts the AP's operation based on client demand, balancing performance and energy savings.

> **Note**
>
> Spatial stream changes are inhibited on any radio interface with connected clients, except when the calendar profile expires.

Smart energy scenarios

Access point power save scenarios.

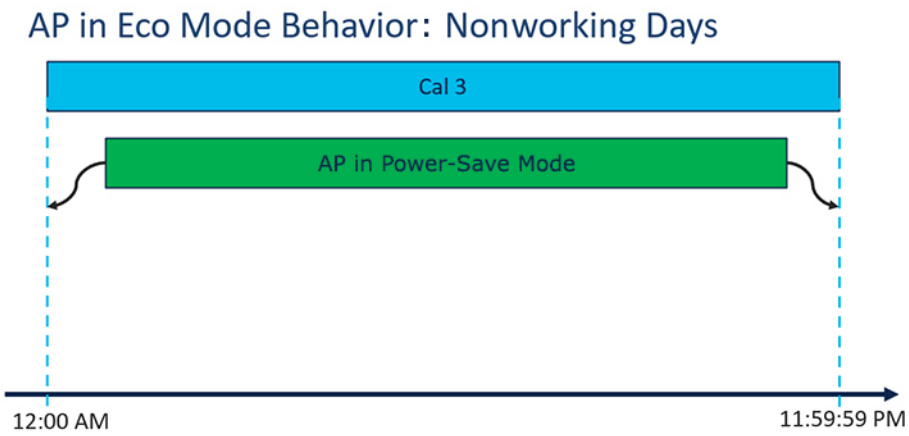
A smart energy AP scenario is a situation where



- APs implement energy-saving modes
- adjust power modes to optimize energy efficiency, and
- apply PoE power policies based on calendar profiles.

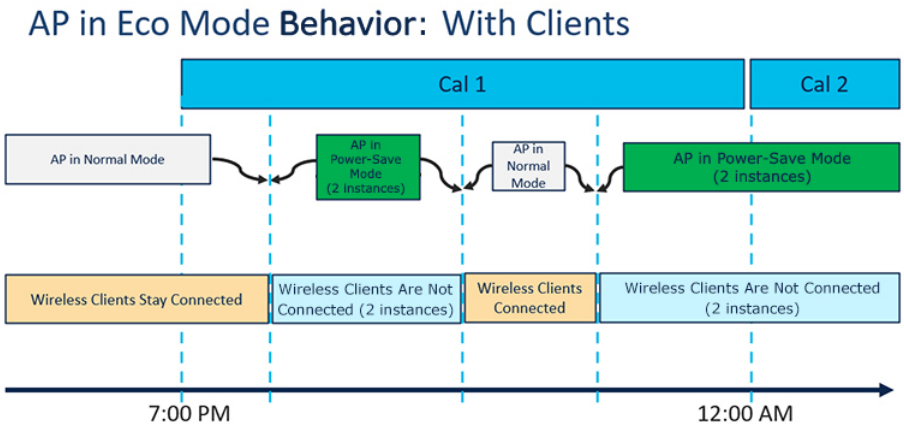
The power Save feature helps APs enter a power-save mode or low-power mode by associating a calendar with the corresponding power profile. This feature is aimed at conserving energy during periods with lower activity, such as after hours.

Examples



- AP in eco mode behavior on working days: On working days, from 7:00 a.m. to 7:00 p.m, the AP functions in normal mode or fixed mode when the maximum number of clients connect to the AP. From 7:00 p.m. to 12:00 midnight., the **Cal1** calendar profile timer starts to put the AP in the power-save mode. Likewise, the **Cal2** calendar profile timer starts, and extends the power-save mode from 12:00 a.m. to 7:00 a.m. Again, at 7:00 a.m., the AP goes into normal mode.

  Figure 5: AP in Eco Mode Behavior: Working Days



- AP in eco mode behavior on nonworking days: On nonworking days, the AP enters power-saving mode from 12:00 a.m. to 11:59:59 p.m. The **Cal3** calendar profile is applied here. This profile defines the timer for the power-save mode. This means there are no clients connected to the AP, and the AP is asleep.

  Figure 6: AP in Eco Mode Behavior: Nonworking Days

- AP behavior when clients connect: When clients are connected to the AP, the AP switches to the normal mode based on client connections. For example, in the calendar profile **Cal1**, the AP is in normal mode, because wireless clients are connected to the AP. At 8:00 p.m., clients dissociate from the AP, and the AP goes into power-save mode. When clients enter the AP coverage area at 9:30 p.m., the AP automatically switches from power-save mode to normal mode of operation.

Figure 7: AP in Eco Mode Behavior: With Clients

How AP power save policies work

Summary

Access point power save policies dynamically manage power states using profiles and schedules. The key components involved in the process are:

- Power profile: Defines what interfaces or features are disabled or derated.
- Calendar profile: Specifies the timing to activate power profiles.
- Client threshold: Defines when to override calendar and re-enable services.

Workflow

The process involves these following stages:

1. Admin defines and configures power and calendar profiles.
2. Profiles are mapped in the AP join profile.

3. AP follows calendar-based transitions between power-save and normal mode.
4. Client presence can override power-save mode if above threshold.

Result

The AP maintains optimal power usage while ensuring service availability when clients connect.

Configure power policy profile (GUI)

Configure power policy profile using GUI.

Use the GUI to configure a power policy profile, enabling you to manage power settings for network components effectively.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Power Profile**.
2. Click **Add**.
   The **Add Power Profile** window is displayed.
3. Enter a name and description for your power profile. Ensure the name contains only ASCII characters, up to 128 characters, without leading or trailing spaces.
4. Click **Add** to add rules for the power profile.
5. Enter a unique sequence number in the **Sequence number** field to designate the priority for power disablement of the component. A sequence number of zero indicates the component is disabled first.
6. From the **Interface** and **Interface ID** drop-down list, choose interface and interface ID to designate to the component for which the power derating rule applies.
7. From the **Parameter** and **Parameter value** drop-down list, choose the values depending on the interface you have previously chosen.

   For example, if you chose **Ethernet** as an interface, you can further customize the rule for the interface by choosing the associated speed. This rule ensures that the AP disables power for the Ethernet interface that is operating at a higher speed, and thereby consuming more power.
8. Click the check mark to save and then click **Apply to Device**.

After configuration, you can effectively manage power for network components.

Configure a power policy profile (CLI)

Configure a power policy profile using commands.

Set up a power policy profile to manage AP energy by configuring Ethernet and USB components through the CLI.

Before you begin

Make sure you activate at least one radio interface before configuring a power policy profile.

Procedure

1. Enter global configuration mode.

   Example

```
Device# configure terminal
```

2. Configure the power policy profile.

   Example

   ```
   Device(config)# wireless profile power power-profile-name
   ```

3. Configure the power policy for Ethernet.

   Example

   ```
   Device(config-wireless-power-profile)# 10 ethernet gigabitethernet1 speed
   1000mbps
   ```

   sequence-number: You can derate the AP based on the sequence number you enter. The same combination of interface identifiers and parameter values does not appear in another sequence number. The same interface with the same parameter can appear multiple times with different parameter values, however, the parameter value that yields the lowest power consumption is the one that gets selected, irrespective of the sequence number if there is active calendar.

   Note

   - The Ethernet interface is used to join the controller. The uplink interface is not disabled even if it is defined in the power policy.
   - Ethernet speed configuration is not operational in Cisco IOS XE 17.8.1 and later releases.

4. Configure the power policy for USB.

   Example

   ```
   Device(config-wireless-power-profile)# 60 usb 0 state disable
   ```

The power policy profile is successfully configured, allowing efficient management of power resources through defined configurations for Ethernet and USB interfaces.

Configure a calendar profile (GUI)

Configure a calendar profile using the GUI.

Set up calendar profiles to define daily, weekly, or monthly recurrence schedules applied to configurations like power management on APs.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Calendar**.
2. Click **Add**.

   The **Add Calendar Profile** window is displayed.

3. Enter a name for the calendar profile. Names must include ASCII characters up to 32 in length, with no leading or trailing spaces.
4. From the **Recurrence** drop-down list, choose the schedule for which you want to create a profile.
5. Select the **Start Time** and the **End Time** for the recurrence schedule.

> **Note**
>
> - For daily recurrences, you can select the start time and end time. For example, if you want the AP to derate the power on certain interfaces between 7 p.m. to 7 a.m. daily, or if you want the controller to not allow any clients to be associated during this period, you can set up this daily recurrence schedule.
>
> To cover this timespan, you must create two calendar profiles, one for 7 p.m. till 23:59:59, and another one from midnight to 7 a.m. of the next calendar day, and map it to the same power profile. Assign it to the AP Join profile after completing this step.
> - For weekly recurrences, select the specific days of the week along with the start and end time.
> - For monthly recurrence, select the specific days of the month along with the start and end time.

6. Click **Apply** to save the configuration.

The calendar profile is applied to manage schedules as defined to influence device behavior based on the recurrence schedule.

Configure a calendar profile (CLI)

Configure a calendar profile using commands.

Configure a calendar profile to automatically schedule device operations based on defined timing parameters.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a calendar profile. Enter the calendar profile configuration mode.

   Example

   ```
   Device# wireless profile calendar-profile name <i>ap_power_calendar</i>
   ```

   Here, **name** refers to the name of the calendar profile.

3. Configure daily recurrence for daily profile.

   Example

   ```
   Device(config-calendar-profile)# recurrence daily
   ```

4. Configure the start time and end time for the calendar profile.

   Example

   ```
   Device(config-calendar-profile)# start 16:00:00 end 20:00:00
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-calendar-profile)# end
   ```

The device uses the specified calendar profile to manage operations according to the configured timings.

Configure a power policy in an access point join profile (GUI)

Configure a power policy in an AP join profile using GUI.

Configure a power policy using a power profile or a mapped configuration of a power profile with a calendar profile in an AP join profile.

During an AP join session, you can use a power profile or a mapped configuration of a power profile and a calendar profile. Map up to five combination profiles (calendar and power) per AP profile.

Before you begin

Ensure that the power profile and calendar profile are created and displayed in the respective drop-down lists in the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.

   The **Add AP Join Profile** window is displayed.

2. Click the **AP** tab.
3. Under the AP tab, click the **Power Management** tab.
4. From the **Regular Power Profile** drop-down list, choose the power profile.

   The AP derates power based on the priority list that you configured.

   > **Note**
   >
   > If you want the AP to apply the power profile configuration during a specific time period, choose the **Calendar Profile** and map it to the power profile from the drop-down list.

5. Click the check mark to associate the mapping.
6. Click **Apply to Device** to save the configuration.

The AP adjusts its power settings based on designated profiles and according to set priorities and calendar schedules.

Map a power profile under an AP profile (CLI)

Map a Power Profile Under an AP Profile using commands.

Configure a power profile mapping in an AP profile using CLI commands.

Before you begin

Ensure that you have defined a calendar profile in the wireless profile, before you map the calendar profile to an AP join profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)#  ap profile  ap-profile-name
   ```

3. Configure the AP power profile.

   Example

   ```
   Device(config-ap-profile)#  power-profile  power-profile-name
   ```

   This power profile is used during non-calendar hours to meet the power budget provided by the switch connected to the AP.

4. Map a calendar profile to the AP profile. Enter the AP profile calendar configuration mode.

   Example

   ```
   Device(config-ap-profile)#  calendar-profile  ap-calendar-profile
   ```

5. Map a specific power profile to a specific calendar profile.

   Example

   ```
   Device(config-ap-profile-calendar)# action power-saving-mode
   power-profile power-profile1
   ```

   Maps the power-saving mode action for the calendar profile. Use the **no** form of this command to disable the command.

> **Note**
>
> You can have more than one mapping of calendar profile to power profile.

The selected power profile is now mapped to the calendar profile within the specified AP profile.

Configure client wakeup threshold (CLI)

Configure client wakeup threshold using commands.

Configure the client wakeup threshold on devices to manage power save mode effectively.

This task involves setting a threshold for clients that influences the power save mode of APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the power policy profile.

   Example

   ```
   Device(config)# wireless profile power power-profile1
   ```

3. Configure the client threshold below which the AP can stay in the power save mode.

   Example

   ```
   Device(config-wireless-power-profile)# power-save-client-threshold 5
   ```

   The valid range is between one and 32 clients. The default value is one.

The power save mode configuration is completed successfully for the specified client threshold.

Configure PoE-Out Interface in Power Profile using GUI

Configure PoE-Out Interface in Power Profile through the GUI.

Configure the PoE-Out interface in a power profile through the GUI. This setup is necessary to ensure proper power management of connected devices through an AP.

Before you begin

Enable the RLAN port for the AP.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Power Profile**.
2. Click **Add**.

   The **Add Power Profile** window is displayed.
3. Enter a name and description for the power profile. The name can contain up to 128 ASCII characters, without leading or trailing spaces.
4. Optional: From the **Power Save Client Threshold** counter, select a value to set a limit to the number of client associations with the AP. The default value is 1. The range is between 1 and 32.
5. Click **Add** to create a rule for the PoE-Out interface.

   The **Rule** section is displayed in the window.
6. In the **Rule** section, complete the following steps:
   a) In the **Sequence number** field, enter a unique sequence number to assign the priority in which power should be disabled for the component. A sequence number of 0 indicates that the component should be disabled first.
   b) From the **Interface** drop-down list, choose **Ethernet** as the interface.
   c) From the **Interface ID** drop-down list, choose one of the following interfaces: **LAN1**, **LAN2**, or **LAN3**.
   d) From the **Parameter** drop-down list, choose **POE-out**.

      An AP uses a POE-out port to provide power to another device, like a camera. This selection ensures that the power usage of the port is reduced or shut down at the specified sequence.
7. Click **Apply to Device**.

The power profile is configured, setting the PoE-Out interface according to specified parameters, effectively managing power to connected devices.

Configure PoE-out interface in the power profile

Configure PoE-out interface in power profile using commands.

Configure PoE-out interfaces in your network within a specified power profile using CLI commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure the power policy profile. Enter the wireless power profile configuration mode.

   Example

   ```
   Device(config)# wireless profile power poe-out-power-profile
   ```
3. Disable the PoE-out state.

Example

```
Device(config-wireless-power-profile)# 1 ethernet LAN1 poe-out disable
```

The interface disables the PoE-out state according to the specified power profile settings for optimized power management.

Configuration example of power profile

Configuration example of power profile.

The example shows how to define a power save policy:

```
wireless profile power power-save
            10 radio 5ghz state shutdown
            20 radio secondary-5ghz state shutdown
            30 radio 6ghz state shutdown
            40 usb 0 state disable
```

The example shows how to define a calendar profile:

```
wireless profile calender-profile name eve-to-midnight
            recurrence daily
            start 19:00:00 end 23:59:59
wireless profile calender-profile name midnight-to-morning
            recurrence daily
            start 00:00:00 end 07:00:00
wireless profile calender-profile name weekends
            recurrence weekly
            day Saturday
            day Sunday
            start 00:00:00 end 23:59:59
```

The example shows how to define an AP join profile and map a calendar profile to a power profile:

```
ap profile wireless-prof-site1
                 calendar-profile eve-to-midnight
                  action power-saving-mode power-profile power-save
                 calendar-profile midnight-to-morning
                  action power-saving-mode power-profile power-save
                 calendar-profile weekends
                  action power-saving-mode power-profile power-save
```

Verify access point power policy (GUI)

Verify the AP Power Policy using GUI.

The purpose of this task is to verify the AP Power Policy applied on the Cisco Catalyst 9136 series using the GUI.

To verify the applied configuration on the GUI, use these steps:

Procedure

1. Choose **Monitoring** > **AP Statistics**.
2. Click a Cisco Catalyst 9136 series AP from the list of APs.

   The **General** window is displayed.

3. Click the **Power** tab.

   The **Power Operational Status** and the **AP Fixed Power Policy** details are displayed.

4. Click **OK**.

These steps help verify whether the power policy settings are correctly applied to the AP.

Verify the access point fixed power policy details

Ensure that the access points are operating with the correct power settings by verifying and updating the AP fixed power policy details, which helps maintain optimal network performance and coverage.

To verify the AP fixed power policy details from the list of configured APs, use these steps:

Procedure

---

1. Choose **Configuration** > **Access Points**.
2. Click a Cisco Catalyst 9136 series AP from the list of APs.
   The **Edit AP** window is displayed.
3. Click the **Interfaces** tab.
   The **AP Fixed Power Policy** details are displayed.
4. Click **Update & Apply**.

The AP fixed power policy details will be displayed.

Verify the access point power profile

Verify the AP Power Profile.

To view the calendar profile and its mapping, use this command:

```
Device# show ap profile name default-ap-profile detailed
AP Profile Name                      : default-ap-profile
Description                          : default ap profile
Power profile name                   : power_prof_day
AP packet capture profile            : Not Configured
AP trace profile                     : Not Configured
Mesh profile name                    : default-mesh-profile
Power profile name                   : Not Configured
Calendar Profile
    Profile Name                    : cal47
    Power saving mode profile name : pow_da
    ------------------------------------------------
    Profile Name                    : cal48
    Power saving mode profile name : pow23
    ------------------------------------------------
```

To view the operational details of the AP, use this command:

```
Device# show ap name cisco-ap power-profile summary
AP power derate Capability      : Capable

Power saving mode
Power saving mode profile        : pow2
Associated calendar profile      : cal1
```

```
AP power profile status         : Insufficient De-rating

Interface    Interface-ID       Parameter        Parameter value    Status
-------------------------------------------------------------------------------
Radio        5 GHz              State            DISABLED           Success

Radio        6 GHz              State            DISABLED           Not
Applicable
Ethernet     LAN1               State            DISABLED           Not
Applicable
Radio        2.4 GHz            State            DISABLED           Success

Ethernet     Gig0               Speed            5000 MBPS          Fixed
Policy
```

AP power derate capability is displayed in the output as **Capable** only for those APs that support power policy. For the other APs, it is displayed as **Not Capable**.

In the **show ap name cisco-ap power-profile summary** output, in the power saving mode, the status of the interface configured in the power profile (for example, **pow2**) is applied on the AP, and the AP sends the details (that are displayed in the show command) such as, the name of the power saving profile and the associated calendar profile.

The table that is displayed shows the interfaces and the parameter status of the power saving profile. The AP sends the information as to which of the interfaces are disabled. For example, if the AP does not have a 6-GHz radio interface, the **Status** is displayed as **Not Applicable**. If the interfaces are applied without any errors, then **Success** is displayed.

Note

When the AP uses the fixed power policy, due to inactive calendar or client connectivity, the interfaces are not displayed in the power profile summary if their status is UP on the AP.

Verify radio spatial streams

Verify radio spatial streams.

To view the configuration and operational details of radio spatial stream rules in the power profile, run these commands:

```
Device# show wireless profile power detailed wireless_pow_profile_name
Power profile name              : wireless_pow_profile_name
-----------------------------------------------
Description                     :
.
.
Seq No       Interface    Interface-id       Parameter        Parameter value
-------------------------------------------------------------------------------
100          Radio        6 GHz              Spatial Stream   2 x 2

200          Radio        5 GHz              Spatial Stream   8 x 8

400          USB          USB0               State            DISABLED

500          Ethernet     Gig0               Speed            100 MBPS

600          Radio        6 GHz              State            DISABLED

700          Radio        2.4 GHz            State            DISABLED
```

```
900          Radio        5 GHz              State            DISABLED
```

```
Device# show ap name cisco-ap-name power-profile summary
AP power derate Capability      : Capable

AP fixed power policy
---------------------

Interface    Interface-ID       Parameter        Parameter value    Status
-------------------------------------------------------------------------------
Ethernet     Gig0               Speed            5000 MBPS          Fixed
Policy
Radio        2.4 GHz            Spatial Stream   4 x 4              Fixed
Policy
Radio        5 GHz              Spatial Stream   8 x 8              Fixed
Policy
Radio        Sec 5 GHz          Spatial Stream   4 x 4              Fixed
Policy
USB          USB0               State            DISABLED           Fixed
Policy
```

Verify client threshold

Verify client threshold.

To view the client threshold details, run this command:

```
Device# show wireless profile power detailed profile1
Power profile name             : profile1
-----------------------------------------------
Description                    : Power profile 1
Power save client threshold    : 5
Seq No       Interface    Interface-id       Parameter        Parameter value
-------------------------------------------------------------------------------
0             Radio        6 GHz             State              DISABLED
1             Radio        5 GHz             Spatial Stream     1 x 1
2             Radio        2.4 GHz           Spatial Stream     2 x 2
3             USB          USB0              State              DISABLED
```

Verify PoE-out details

Verify PoE-out details.

To view the PoE-out details in the wireless power profile, run these commands:

```
Device# show wireless profile power detailed poe-out_profile_name
Power profile name             : poe-out_profile_name
-----------------------------------------------
Description                    : profile-description
Seq No       Interface    Interface-id       Parameter        Parameter value
-------------------------------------------------------------------------------
10 ...
20           Ethernet     LAN 1              POE_OUT          DISABLED
30 ...
```

```
Device# show ap name Cisco-Ap1 power-profile summary
AP power derate Capability      : Capable
```

```
AP fixed power policy
---------------------

Interface    Interface-ID       Parameter        Parameter value    Status

Policy
...
```

31 Real-Time Access Points Statistics

Topics:

- Access point real-time statistics

Access point real-time statistics

Introduces access point real-time statistics, covering SNMP traps, monitoring restrictions, and configuration procedures via GUI and CLI. Details radio monitoring, verification commands, and guides AP performance management for optimal wireless network operations.

An access point real-time statistic is a tool that

- allows tracking of CPU utilization and memory usage of an AP,
- monitors the health of an AP, and
- generates real-time statistics from an AP.

Feature history

Release	Feature	Feature information
Cisco IOS XE 17.7.1	Real time access point statistics	The system implements this feature with AP threshold values between 0 and 50. From Cisco IOS XE Cupertino 17.7.1 onwards, you can reset radios based on the AP's real-time statistics. If Tx or Rx counters do not increment during a sampling period, a radio reset is triggered. The following commands are introduced: • **show wireless stats ap join summary** • **show wireless stats ap history**
Cisco IOS XE 17.5.1	Real time access point statistics	Starting from Cisco IOS XE 17.5.1, you can monitor both CPU utilization and memory usage to assess the health of an AP through generated real-time statistics.

Supporting reference information

SNMP traps are sent out when the threshold is crossed. The sampling period and statistics interval can be configured using SNMP, YANG, and CLI.

From Cisco IOS XE 17.7.1 release onwards, for radio monitoring, you can reset the radios based on the statistics sent by the AP for a sampling period. When you configure the radios in the controller, if there is no increment in the Tx or Rx statistics when the radio is up, then the radio reset is triggered.

SNMP traps and intervals for APs

AP real-time statistics support these capabilities:

- SNMP Traps: Triggers notifications when CPU or memory usage crosses configured thresholds for APs and controllers.

- Sampling Period and Statistics Interval: Can be configured using SNMP, YANG, and CLI to control how often statistics are collected and reported.

Restrictions for AP radio monitoring statistics

AP radio monitoring statistics restrictions.

You cannot reset the radio firmware from the controller. The controller will shut and then restart the radio if the Rx or Tx count does not increase for a radio slot within a specified period.

Configure access point real time statistics (GUI)

Configure access point real time statistics using GUI.

This task helps you configure real-time statistics for access points using a graphical user interface, allowing you to effectively monitor and manage AP behavior.

Procedure

1. Choose **Configuration > Tags & Profiles > AP Join**.
2. Click **Add**. The **Add AP Join Profile** page is displayed.
3. Under the **AP** tab, click the **AP Statistics** tab.
4. In the **System Monitoring** section:
   - Enable **Monitor Real Time Statistics** to get calculated statistics and alarms of the AP.
   - To receive an alarm when the upper threshold is surpassed for parameters such as CPU utilization and memory, enable **Trigger Alarm for AP**.
   - Enter the threshold percentage for CPU and memory usage in the **CPU Threshold to Trigger Alarm** field and **Memory Threshold to Trigger Alarm** fields, respectively. The valid range is between 0 and 50. An SNMP trap is sent out when this threshold is crossed.
   - In the **Interval to Hold Alarm** field, enter the time for which the alarm is held before it gets triggered. The range is between 0 and 3600 seconds.
   - In the **Trap Retransmission Time** field, enter the time between retransmissions of the alarm. The range is between 0 and 65,535 seconds.
   - To define how often data should be collected from the AP, enter a value in the **Sampling Interval** field. The range is between 720 and 3600 seconds.
   - To define the interval at which AP statistics are to be calculated, enter a value in the **Statistics Interval** field. The range is between 2 and 900 seconds.
   - To automatically reload the AP when there is high CPU and memory usage in the defined sampling interval, select the **Reload the AP** check box.
5. Under the **Radio Monitoring** section:
   - Select the **Monitoring of AP Radio stuck** check box to verify that the Tx and Rx statistics of the AP are updated each time the payloads are coming in from the AP to the controller.
   - To generate an alarm for the radio of the AP when there is no increment in the Tx and RX statistics for the payloads, select the **Alarms for AP Radio stuck** check box.
   - Select the **Reset the stuck AP Radio** check box to recover the radio from the bad state. A radio admin state payload will be sent from the controller to toggle the radio and the radio will be shut when there is no increment in the Tx and Rx statistics.

- To define how often data should be collected from the radio, enter a value in the **Sampling Interval** field. The valid range is between 720 and 3600 seconds.

6. Click **Apply to Device** to save the configuration.

The AP monitors real-time statistics and triggers alarms based on defined thresholds to aid you in efficiently managing AP resources.

Configure access point real-time statistics (CLI)

Configure real-time access point statistics using commands.

This task provides instructions on how to configure real-time statistics for an access point using CLI commands.

This task is intended for network administrators who need to monitor and configure various system parameters on a Cisco access point, particularly real-time statistics related to performance monitoring.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile. The default AP join profile name is *default-ap-profile*.

   Example

   ```
   Device(config)# ap profile doc-test
   ```

3. Optional: Configure the statistics timer.

   Example

   ```
   Device(config-ap-profile)# stats-timer 60
   ```

   This step configures the interval for the statistics reports coming from the AP, with values ranging from 0 to 65535 seconds.

4. Optional: Enable monitoring for AP system.

   Example

   ```
   Device(config-ap-profile)# statistics ap-system-monitoring enable
   ```

5. Enable alarms for AP system monitoring.

   Example

   ```
   Device(config-ap-profile)# statistics ap-system-monitoring alarm-enable
   ```

6. Define the hold time for system monitoring alarms on the AP.

Example

```
Device(config-ap-profile)# statistics ap-system-monitoring alarm-hold-time
400
```

The values range from 0 to 3600 seconds.

7. Define the retransmission interval for the trap alarms.

Example

```
Device(config-ap-profile)# statistics ap-system-monitoring
alarm-retransmit-time 100
```

Set the interval, with values from 0 to 65535 seconds, for retransmitting trap alarms when conditions persist.

8. Define the CPU usage threshold for the AP to trigger alarms.

Example

```
Device(config-ap-profile)# statistics ap-system-monitoring cpu-threshold 90
```

> **Note**
>
> From Cisco IOS XE 17.7.1 release onwards, the threshold value for triggering alarms is from 0 to 100%.

9. Define the memory usage threshold on the AP to trigger alarms.

Example

```
Device(config-ap-profile)# statistics ap-system-monitoring mem-threshold 90
```

The percentage threshold for memory usage on the AP to trigger is from 0 to 100%.

> **Note**
>
> From Cisco IOS XE 17.7.1 release onwards, the memory usage threshold to trigger alarms ranges from 0 to 100%.

10. Optional: Configure the statistics sampling interval.

Example

```
Device(config-ap-profile)# statistics ap-system-monitoring sampling-interval
 600
```

The interval can range from 2 to 65535 seconds.

11. Exit from AP profile configuration mode and return to global configuration mode.

Example

```
Device(config-ap-profile)# exit
```

12. Enable sending AP-related trap flags for statistics that exceed set thresholds.

Example

```
Device(config)# trapflags ap ap-stats
```

Traps are sent when statistics exceed the configured thresholds, enabling alerts and automated responses.

The statistics of the access point have been configured, enabling real-time monitoring and alarm triggering for system performance parameters.

```
                Device(config)# ap profile default-policy-profile
                Device(config-ap-profile)# statistics ap-system-monitoring
enable
                Device(config-ap-profile)#statistics ap-system-monitoring
sampling-interval 600
                Device(config-ap-profile)#statistics ap-system-monitoring
alarm-enable
                Device(config-ap-profile)#statistics ap-system-monitoring
alarm-hold-time 3
                Device(config-ap-profile)#statistics ap-system-monitoring

Configure the access point radio monitoring statistics (CLI)

Configure access point radio monitoring statistics using commands.

Learn how to configure monitoring statistics for AP radios to enable stuck radio statistics, alarms, and actions for optimal performance.

These steps help configure AP radio monitoring statistics:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an AP profile and enter the AP profile configuration mode.

Example

```
Device(config)# ap profile test1
```

3. Enable the monitoring of AP radio stuck statistics.

   Example

   ```
   (config-ap-profile)#statistic ap-radio-monitoring enable
   ```

4. Enable the alarm for AP radio stuck statistics.

   Example

   ```
   (config-ap-profile)#statistic ap-radio-monitoring alarm-enable
   ```

5. Specify the sampling interval in seconds.

   Example

   ```
   (config-ap-profile)# statistic ap-radio-monitoring action reload-ap interval850
   ```

   The values range from 720 to 3,600 seconds.

6. Generate an alarm and reset the radio if the radio is stuck.

   Example

   ```
   (config-ap-profile)# statistic ap-radio-monitoring action radio-reset
   ```

7. Reload the AP.

   Example

   ```
   (config-ap-profile)# statistic ap-system-monitoring action reload-ap
   ```

The AP radio monitoring statistics help identify stuck radios and automatically take corrective actions to ensure optimal performance.

```
Device(config)# ap profile test1
Device(config-ap-profile)# statistics ap-radio-monitoring enable
Device(config-ap-profile)#statistic ap-radio-monitoring alarm-enable
Device(config-ap-profile)#statistic ap-radio-monitoring sampling-interval 750
Device(config-ap-profile)# statistic ap-radio-monitoring action radio-reset
Device(config-ap-profile)#statistic ap-system-monitoring action reload-ap
```

Monitor access point real-time statistics (GUI)

Monitor AP real-time statistics using GUI.

This task enables network administrators to monitor access point performance and diagnose potential issues by viewing real-time statistics.

Procedure

---

1. Choose **Monitoring** > **Wireless** > **AP Statistics**.

2. Click the **General** tab.
3. Click an AP name. The **General** window is displayed.
4. To view the AP Statistics data, click the **AP Statistics** tab.

   These types of information are displayed:

   - **Memory alarm last send time**: Displays the time of the last memory trap sent.
   - **Memory Alarm Status**: Displays the state of the memory alarm. An alarm can be **ACTIVE**, **INACTIVE**, **INACTIVE_SOAKING**, **ACTIVE_SOAKING**. An alarm is soaked until the configured hold time has passed.
   - **Memory alarm raise time**: Displays the last time the memory alarm was active.
   - **Memory alarm clear time**: Displays the last time the memory alarm was inactive.
   - **Last statistics received**: Displays the time of the last statistics report received from the AP.
   - **Current CPU Usage**: Displays the latest percentage of CPU usage reported.
   - **Average CPU Usage**: Displays the average CPU usage calculated.
   - **Current Memory Usage**: Displays the latest percentage of memory usage reported.
   - **Average Memory Usage**: Displays the average memory usage calculated.
   - **Current window size**: Displays the window size. The window size is calculated by dividing the statistics interval by the sampling interval. The average CPU and memory usage is calculated by the window size.
   - **CPU alarm last send time**: Displays the time of the last CPU trap sent.
   - **CPU Alarm Status**: Displays the state of the CPU alarm. An alarm can be **ACTIVE**, **INACTIVE**, **INACTIVE_SOAKING**, **ACTIVE_SOAKING**. An alarm is soaked until the configured hold time has passed.
   - **CPU alarm raise time**: Displays the last time the CPU alarm was active.
   - **CPU alarm clear time**: Displays the last time the CPU alarm was inactive.

5. Click **OK**.

The current statistics for the selected access point are displayed, allowing for comprehensive monitoring and analysis of AP performance metrics.

Verify access point real-time statistics

Verify access point real-time statistics.

To verify AP real-time statistics, run this command:

```
Device# show ap config general | section AP statistics
!Last Statistics
AP statistics : Enabled
Current CPU usage : 4
Average CPU usage : 49
Current memory usage : 35
Average memory usage : 35
Last statistics received : 03/09/2021 15:25:08
!Statistics Configuration
Current window size : 1
Sampling interval : 30
Statistics interval : 300
AP statistics alarms : Enabled
!Alarm State - Active, Inactive, Inactive_Soaking, Inactive_Soaking
```

```
Memory alarm status : Active
Memory alarm raise time : 03/09/2021 15:24:29
Memory alarm clear time : NA
Memory alarm last send time : 03/09/2021 15:24:59
CPU alarm status : Inactive
CPU alarm raise time : 03/09/2021 15:24:25
CPU alarm clear time : 03/09/2021 15:25:05
CPU alarm last send time : 03/09/2021 15:25:05
!Alarm Configuration
Alarm hold time : 6
Alarm retransmission time : 30
Alarm threshold cpu : 30
Alarm threshold memory : 32
```

To verify that the statistics reporting period is accurate, run this command:

```
Device# show ap config general | i Stats Reporting Period
Stats Reporting Period : 10
```

32 AP Configuration

Topics:

- AP console configurations
- AP audit configuration
- Radio support for specified slot number
- XOR radio support
- Receiver only dual-band radio support
- OFDMA support for 802.11ax APs
- Cisco flexible antenna port
- Environmental sensors in APs
- CAPWAP LAG support
- CAPWAP message aggregation

AP console configurations

Explains how AP console configurations enable or restrict console access to access points and outlines their relation to security modes and configuration methods.

An AP console configuration is a controller-managed setting that

- allows administrators to enable or disable console access for APs from the controller
- operates independently from the FIPS or high-security (CC) mode in certain software versions, and
- can be configured through both the controller GUI and CLI.

Enable the console independently of FIPS mode by configuring the AP join profile. If you enable CC mode, console and SSH access are disabled. Any AP console settings configured in the AP profile are overridden by CC mode.

Feature history

Table 40: Feature history for AP console configurations

Feature Name	Release Information	Feature Description
AP console configurations	Cisco IOS XE 17.9.1	This feature allows you to configure the AP console from the controller. In Cisco IOS XE Cupertino 17.8.x and earlier releases, the AP console could be disabled from the controller, only by enabling the Federal Information Processing Standard (FIPS) mode or the Common Criteria (CC) mode.

Configure the AP console (GUI)

Configure the AP console using GUI.

Enable serial console access for an AP via the management interface.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. In the **Management** tab, go to the **Telnet/SSH Configuration** section. Check the **Serial Console** check box.
3. Set the **Console Speed**. The available options are: **9600**, **115200** and **None**.

   None sets the **no console speed**.
4. Click **Apply to Device**.

Configure the AP console (CLI)

Configure the AP console using commands.

Enable or disable the AP serial console port by configuring the AP profile.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Enable the AP serial console port.

   Example

   ```
   Device(config-ap-profile)# console
   ```

   Use the **no** form of this command to disable the AP serial console port.

4. Configure the AP console speed.

   Example

   ```
   Device(config-ap-profile)# console speed { 9600 | 115200}
   ```

   The supported speeds are 9600 and 115200 bps.

   Use the **no** form of the command to maintain the current configuration and retain the AP's console speed.

Verify the AP console status

Verify the AP console status.

To verify the AP console status from the controller, run the command:

```
Device# show ap config general | include ap-Name | console
Cisco AP Name : CiscoAP
================================================
Cisco AP Identifier : 6XXX.bXXX.aXXX

SSH State : Enabled
Serial Console State : Enabled
```

AP audit configuration

Explains how AP audit configuration enables real-time and periodic detection and reporting of synchronization issues between wireless controllers and access points.

An AP audit configuration is a wireless network management feature that

- detects and reports synchronization issues between the controller and an AP
- provides both real-time and periodic comparison of configuration and operational states, and
- supports automated error reporting using syslog for discrepancies.

In Cisco IOS XE Amsterdam, Release 17.3.1, two methods are implemented to support AP audit configuration.

- Config Checker
- Config Audit

Config Checker audits the application of wireless policies during the AP join phase. Any discrepancies detected at this stage are reported to the controller. This function is built-in and cannot be disabled. When you configure AP attributes such as name, IP address, controller information, tag, mode, radio mode, and radio admin state, the AP parses the CAPWAP payload configuration from the controller. It then reports any detected errors to the controller using the proper code. If a discrepancy is detected, the controller flags errors using the syslog.

Config Audit periodically compares operational states between an AP and the controller after the AP joins and while it remains connected. When discrepancies are found, Config Audit reports them immediately on the controller. You can view a consolidated report at any time. By default, this functionality is disabled. You can configure the periodic auditing interval.

Use the **ap audit-report** command to enable and configure audit report parameters. When you trigger the audit, the AP sends its configurations to the controller. The controller compares these configurations with the current settings. If there is a mismatch, the controller reports the error using syslog.

Feature history

Table 41: Feature history for AP audit configuration

Feature Name	Release Information	Feature Description
AP audit configuration	Cisco IOS XE 17.3.1	This feature enables real-time and periodic detection, reporting, and automated syslog alerting of synchronization discrepancies between the wireless controller and APs.

Restrictions for AP audit configuration

AP audit configuration restriction.

- Config checker alerts are available only through the syslog.
- IOS AP is not supported.
- Audit reports do not synchronize from the active controller to the standby controller. After SSO, you cannot access audit reports until the next reporting interval for already connected APs.
- Audit reports are not available when an AP operates in standalone mode.
- This feature is supported only on APs in FlexConnect mode.

Configure AP audit parameters (CLI)

Configure AP audit parameters using commands.

Enable and customize AP audit reporting to monitor and compare AP operational states against controller expectations.

The AP sends state view details to the controller, and the controller compares it with what it perceives as the AP state. This feature is disabled by default.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable audit reporting.

   Example

   ```
   Device(config)# ap audit-report enable
   ```

3. Configure the AP audit reporting interval.

   Example

   ```
   Device(config)# ap audit-report interval interval 1300
   ```

   The default value for interval is 1440 minutes. The valid range is from 10 to 43200.

Verify AP audit report summary

Verify AP audit report summary.

To verify the AP audit report summary, use the **show ap audit-report summary** command:

```
Device# show ap audit-report summary
WTP Mac                    Radio                   Wlan                 IPv4

Radio support for specified slot number

Explains which radio modules are supported in each slot number.

Configure 2.4-GHz radio support for the specified slot number (CLI)

Configure 2.4-GHz radio support for the specified slot number.

Enable and configure 2.4-GHz radio features for a specified AP slot using commands.

> **Note**
>
> The term **802.11b radio** or **2.4-GHz radio** are used interchangeably.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enable Spectrum Intelligence (SI) for the dedicated 2.4-GHz radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 SI
   ```

   For more information, see the *Spectrum Intelligence* section in this guide. In this context, ***0*** refers to the Slot ID.

3. Configure 802.11b antenna hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 antenna {ext-ant-gain
   antenna_gain_value | selection [ internal | external ]}
   ```

   - **ext-ant-gain** : configures the 802.11b external antenna gain. *antenna_gain_value* : the external antenna gain value, specified in multiples of 0.5 dBi units. The valid range is from zero to 40, with a maximum gain of 20 dBi.
   - **selection** : configures the 802.11b antenna to use either the internal or external option.

   > **Note**
   >
   > - For APs that support self-identifying antennas (SIA), the gain depends on the antenna and not the AP model. The AP automatically learns the gain, so no controller configuration is necessary.
   > - For APs that do not support SIA, the AP sends the antenna gain in the configuration payload. The default antenna gain depends on the AP model.
   > - Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, they do not automatically detect SIA antennas or apply the correct external gain.

4. Configure beamforming for the 2.4-GHz radio hosted on slot 0 for a specific AP.

Example

```
Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 beamforming
```

5. Configure advanced 802.11 channel assignment parameters for the 2.4-GHz radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 channel {channel_number | auto}
   ```

6. Enable CleanAir for 802.11b radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 cleanair
   ```

7. Configure 802.11n antenna for 2.4-GHz radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 dot11n antenna {A | B | C |
   D}
   ```

   Here, are the descriptions of various options:

   A : A is the antenna port A.

   B : B is the antenna port B.

   C : C is the antenna port C.

   D : D is the antenna port D.

8. Disable 802.11b radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 shutdown
   ```

9. Configure transmit power level for 802.11b radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 24ghz slot 0 txpower {tx_power_level | auto}
   ```

   - *tx_power_level* : is the transmit power level in dBm. The valid range is from one to eight.
   - **auto** : enables auto-RF.

Configure 5-GHz radio support for the specified slot number (CLI)

Configure 5-GHz Radio Support for the Specified Slot Number.

Enable and configure 5-GHz radio features on a selected AP slot.

> **Note**
>
> The term **802.11a radio** or **5-GHz radio** are used interchangeably in this document.

Procedure

1. Enable Spectrum Intelligence (SI) for the dedicated 5-GHz radio hosted on slot 1 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 SI
   ```

   Here, ***1*** refers to the Slot ID.

2. Configure external antenna gain for 802.11a radios for a specific AP hosted on slot 1.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna ext-ant-gain
   antenna_gain_value
   ```

   antenna_gain_value : refers to the external antenna gain value in multiples of .5 dBi units. The valid range is from zero to 40, with the maximum gain of 20 dBi.

   > **Note**
   >
   > - For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, not on the AP model. The AP learns the gain, so controller configuration is not required.
   > - For APs that do not support SIA, the AP sends the antenna gain in the configuration payload. The default antenna gain depends on the AP model.
   > - Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, these APs do not automatically detect SIA antennas or add the correct external gain.

3. Configure the antenna mode for 802.11a radios for a specific AP hosted on slot 1.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna mode {omni | sectorA |
    sectorB}
   ```

4. Configure the antenna selection for 802.11a radios for a specific AP hosted on slot 1.

Example

```
Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 antenna selection {internal |
external}
```

5. Configure beamforming for the 5-GHz radio hosted on slot 1 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 beamforming
   ```

6. Configure advanced 802.11 channel assignment parameters for the 5-GHz radio hosted on slot 1 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 channel {channel_number | auto
    | width [20 | 40 | 80 | 160]}
   ```

   Here,

   channel_number : refers to the channel number. The valid range is from one to 173.

7. Enable CleanAir for 802.11a radio hosted on slot 1 for a given or specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 cleanair
   ```

8. Configure 802.11n for 5-GHz radio hosted on slot 1 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 dot11n antenna {A | B | C | D}
   ```

   Here, are the descriptions of various options:

   A : A is the antenna port A.

   B : B is the antenna port B.

   C : C is the antenna port C.

   D : D is the antenna port D.

   Change the channel hosted on slot 1 for a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 rrm channel 2
   ```

   Here, *channel*: refers to the new channel created using 802.11h channel announcement. The valid range is from one to 173, provided 173 is a valid channel in the country where the AP is deployed.

9. Disable 802.11a radio hosted on slot 1 for a specific AP and configure 802.11a radio hosted on slot 1 for a specific AP.

Example

```
Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 shutdown
```

```
Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 txpower {tx_power_level | auto}
```

- *tx_power_level* : is the transmit power level in dBm. The valid range is from one to eight.
- **auto** : enables auto-RF.

Configure 6-GHz radio support for the specified slot number

Configure 6-GHz radio support for the specified slot number.

Enable and configure 6-GHz wireless radios on a Cisco AP to operate optimally within regulatory requirements.

Before you begin
Set the static channel before you change the channel width. As there are no external antenna APs, antennas must be captive (always internal) for 6-GHz, in accordance with regulatory requirements.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Configure the antenna port for 802.11 6-Ghz radios for a specific AP.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 antenna port {A | B | C | D}
   ```

   Here, are the descriptions of various options:

   A : A is the antenna port A.

   B : B is the antenna port B.

   C : C is the antenna port C.

   D : D is the antenna port D.

3. Configure the antenna selection, either internal or external, for 802.11 6-Ghz radios for a specific AP.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 1 antenna selection {internal |
   external}
   ```

> **Note**
>
> - For APs supporting self-identifying antennas (SIA), the antenna determines the gain. The AP learns the gain automatically; you do not need to configure the controller.
> - For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model.
> - Cisco Catalyst 9120E and 9130E APs support self-identifying antennas (SIA). Cisco Catalyst 9115E APs do not support SIA antennas. Although Cisco Catalyst 9115E APs work with SIA antennas, these APs do not automatically detect SIA antennas or add the correct external gain.

4. Configure advanced 802.11 channel assignment parameters for the 6-GHz radio hosted on slot 3 for a specific AP.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 channel channel_number { auto |
   width [160 | 20 | 40 | 80]}
   ```

   Here, *channel_number* : refers to the channel number. The valid range is from one to 233.

5. Enable basic service set (BSS) color for 802.11 6-Ghz radio for a given or specific AP.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 dot11ax bss-color {bss-color-number
    | auto}
   ```

   Here, *bss-color-number*: refers to the BSS color number. The valid range is from one to 63.

6. Configure the 802.11 6-Ghz radio role

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 radio role {auto | manual
   [client-serving | monitor | sniffer]}
   ```

7. Configure a new channel using 802.11h channel announcement.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 rrm channel 1
   ```

   Here, *channel* : refers to the new channel created using 802.11h channel announcement. The valid range is from one to 233.

8. Disable the 802.11 6-Ghz radio on the Cisco AP.

   Example

   ```
   Device# ap name Cisco-AP dot11 6ghz slot 3 shutdown
   ```

9. Configure 802.11 6-Ghz Tx power level.

Example

```
Device# ap name AP-SIDD-A06 dot11 5ghz slot 1 txpower { tx_power_level | auto}
```

- *tx_power_level* : is the transmit power level in dBm. The valid range is from one to eight.
- **auto** : enables auto-RF.

XOR radio support

Explains the concept of XOR radios in wireless networking and how they enable flexible use of radio hardware for improved network performance.

Dual-band radios in Cisco AP models

Details on dual-band radio support.

A dual-band radio is a device category that

- offers connectivity on more than one frequency band (such as 2.4 GHz and 5 GHz)
- provides flexibility in network configuration, and
- is used in multiple Cisco AP models like the 2800, 3800, 4800, and 9120 series.

Feature history table
Table 42: Feature history table for dual-band radios in Cisco AP models

Feature name	Release information	Feature description
Dual-band (XOR) radio support	Cisco IOS XE 16.10.1	The Dual-band (XOR) radio support offers the ability to serve 2.4 GHz or 5 GHz bands or passively monitor both the bands on the same AP. These APs can be configured to serve clients in 2.4 GHz and 5 GHz bands, or serially scan both 2.4 GHz and 5 GHz bands on the flexible radio while the main 5 GHz radio serves clients.

Key features of dual-band radios in Cisco APs

The XOR radio support can be steered manually or automatically.

- Manual steering of a band on a radio: The band on the XOR radio can only be changed manually.
- Automatic client and band steering on radios: This is managed by the Flexible Radio Assignment (FRA) feature that monitors and changes the band configurations as per site requirements.

Client steering

When a radio moves between bands (from 2.4 GHz to 5 GHz and vice versa), clients need to be steered to get an optimal distribution across radios. When an AP has two radios in the 5 GHz band, client steering algorithms contained in the FRA algorithms are used to steer a client between the same band co-resident radios

Cisco APs and dual-band radios

Cisco 2800, 3800, 4800, and 9120 series AP models are equipped with dual-band (XOR) radios. These models have

- radios that operate on either 2.4 GHz or 5 GHz bands, or
- the ability to passively monitor both the bands on the same AP.

These APs can be configured to serve clients in 2.4 GHz and 5 GHz bands, or serially scan both 2.4 GHz and 5 GHz bands on the flexible radio while the main 5 GHz radio serves clients.

Cisco AP models up to the Cisco 9120 APs are designed to support dual 5 GHz band operations with the *i* model supporting a dedicated Macro or Micro architecture and the *e* and *p* models supporting Macro or Macro. The Cisco 9130AXI APs support dual 5 GHz operations as Macro or Micro cell.The CW9166I supports Macro or Macro cell.

Cisco Catalyst Wireless 9166 AP (CW9166) has XOR function for a dual 5 GHz 4x4 or 5 GHz 4x4 and 6 GHz 4x4 radios. These radios can also be configured as client serving, monitor or as a sniffer interface like the earlier XOR radios.

> **Note**
>
> For all countries that do not support 6 GHz spectrum for use of Wi-Fi, when the Cisco Catalyst Wireless 9166I AP operates as dual 5 GHz, the 5 GHz channels will be locked on both the radios even if slot 2 is disabled or set up for monitoring.

Wi-Fi 7 APs compatibility

For Wi-Fi 7 APs, the XOR radio operates in 2.4 GHz or 5 GHz low band mode (UNII 1-2A). By default, the XOR radio is brought up in 2.4 GHz band. The existing controller dual-band commands are used to switch between 2.4 GHz and 5 GHz bands. When XOR radio is switched to 5 GHz band, the Wi-Fi 7 APs operate in dual 5 GHz mode. To provide enough RF isolation between both 5 GHz radios, both the 5 GHz radios operate in band-locked mode and radio frequency.

Limitations

Limitations for XOR radio support.

These are the limitations for XOR radio support:

- RF measurement is disabled when a static channel is configured on slot 1. As a result, the dual-band radio slot 0 operates only with 5 GHz radios and not in the monitor mode. When slot 1 radio is disabled, RF measurement will not run, and the dual band radio slot 0 will be only on 2.4 GHz radio.
- Only one of the 5 GHz radios can operate in the UNII band (100 to 144), due to an AP limitation to maintain the power budget within the regulatory limit.

Configure default XOR radio support (CLI)

Configure Default XOR Radio Support using commands.

Complete this task to configure the basic settings for XOR radio support.

Before you begin

> **Note**
>
> The default radio points to the XOR radio hosted on slot 0.

Procedure

1. Enable the priviledged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Configure the 802.11 dual-band external antenna gain on the AP.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band antenna ext-ant-gain
   antenna_gain_value
   ```

   Enter external antenna gain value in multiple of .5 dBi units (that is, an integer value 4 means 4 x 0.5 = 2 dBi of gain).

3. Shut down the default dual-band radio.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band shutdown
   ```

   Use the **no** form of the command to enable the radio.

4. Switch to the client-serving mode of the AP.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band role manual client-serving
   ```

5. Switch to the 2.4 GHz radio band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band band 24ghz
   ```

The basic configuration of the XOR radio is completed.

Example

```
Device> enable
Device# ap name ap-name  dot11 dual-band antenna ext-ant-gain 2
Device# ap name ap-name  dot11 dual-band shutdown
```

```
Device# Device# ap name ap-name  dot11 dual-band role manual client-serving
Device# Device# ap name ap-name  dot11 dual-band band 24ghz
```

What to do next

Continue with the configuration steps listed in the "Configure advanced settings" to complete the configuration.

Configure advanced settings (CLI)

Complete this task to configure the advanced settings for XOR radio support, such as, transmit power, channel, channel width, CleanAir settings and so on.

Procedure

1. Configure the transmit power for the radio on the AP.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band txpower {transmit_power_level | auto}
   ```

   Note

   When an FRA-capable radio (slot 0 on 9120 AP[for instance]) is set to Auto, you cannot configure static channel and Txpower on this radio.

   If you want to configure static channel and Txpower on this radio, you will need to change the radio role to Manual Client-Serving mode.

   This note is not applicable for Cisco Catalyst Wireless 9166 AP (CW9166).

2. Configure the channel number for the dual band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel 40
   ```

   The range of the *channel-number* is from 1 to 173.

3. Optional: Enable the auto channel assignment for the dual-band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel auto
   ```

4. Configure the channel width for the dual band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel width {20 MHz | 40 MHz | 80
    MHz | 160 MHz}
   ```

5. Enable the Cisco CleanAir management on the dual-band radio.

Example

```
Device# ap name ap-name  dot11 dual-band cleanair
```

6. Configure a band for the Cisco CleanAir feature.

   Example

   ```
   Device# ap name ap-name [no] dot11 dual-band cleanair band 5 GHz
   ```

   Selects a band for the Cisco CleanAir feature.

   Use the **no** form of this command to disable the Cisco CleanAir feature.

7. Configure the 802.11n dual-band antenna and antenna ports selection for a specific AP.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band dot11n antenna {A | B | C | D}
   ```

   Here, A, B, C, and D are the antenna ports.

The configuration of the additional features for dual-band (XOR) radios are completed.

Example

```
Device# ap name ap-name  dot11 dual-band txpower auto
Device# ap name ap-name  dot11 dual-band channel 40
Device# ap name ap-name  dot11 dual-band channel width 40 MHz
Device# ap name ap-name  dot11 dual-band cleanair
Device# ap name ap-name [no] dot11 dual-band cleanair band 5 GHz
Device# ap name ap-name  dot11 dual-band dot11n antenna A
```

Configure XOR radio support for the specified slot number (GUI)

Configure XOR radio support for the specified slot number using GUI.

Complete this task to configure XOR radio for the specified slot number.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Dual-Band Radios** section, select the AP for which you want to configure dual-band radios.

   The AP name, MAC address, CleanAir capability and slot information for the AP are displayed. If the Hyperlocation method is HALO, it displays the antenna PID and antenna design specifics.

3. Click **Configure**.
4. In the **General** tab, set the **Admin Status** as required.
5. Set the **CleanAir Admin Status** field to Enable or Disable.
6. Click **Update & Apply to Device**.

The XOR radio support for the specified slot number has been configured.

Configure XOR radio support for the specified slot number (CLI)

Configure XOR Radio Support for the Specified Slot Number using commands.

Complete this task to configure XOR radio for a specified slot number.

Procedure

1. Enable the priviledged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Configure dual-band antenna for the XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 antenna ext-ant-gain
   external_antenna_gain_value
   ```

   Here, *external_antenna_gain_value* is the external antenna gain value in multiples of .5 dBi unit. The range is from 0 to 40.

   Note

   - For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration.
   - For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model.

3. Configure the current band for XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 band {24ghz | 5ghz}
   ```

4. Configures dual-band channel for the XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 channel {channel-number | auto
    | width [160 | 20 | 40 | 80]}
   ```

   The range of the *channel_number* is from 1 to 165.

5. Enable the Cisco CleanAir feature for dual-band radios hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 cleanair band {24Ghz | 5ghz}
```

6. Configure 802.11n dual-band parameters hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 dot11n antenna {A | B | C |
   D}
   ```

   Here are the antenna configurations.

   A : Enables antenna port A.

   B : Enables antenna port B.

   C : Enables antenna port C.

   D : Enables antenna port D.

7. Configure dual-band role for the XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 role {auto | manual
   [client-serving | monitor]}
   ```

   Here are the dual-band roles.

   - **auto** : refers to the automatic radio role selection.
   - **manual** : refers to the manual radio role selection.

> **Note**
>
> When Flexible Radio Assignment (FRA) is disabled, XOR radios whose roles were changed by Radio Resource Management (RRM) might not automatically revert to their default radio role. To restore an individual AP to the default client-serving role, use the these commands:
>
> ```
> Device# ap name ap-name dot11 dual-band slot 0 shutdown
> ```
>
> ```
> Device# ap name ap-name dot11 dual-band slot 0 role manual client-serving
> ```
>
> ```
> Device# ap name ap-name dot11 dual-band slot 0 band 24ghz
> ```
>
> ```
> Device# ap name ap-name no dot11 dual-band slot 0 shutdown
> ```

8. Disable dual-band radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name [no] dot11 dual-band slot 0 shutdown
   ```

   Use the **no** form of this command to enable the dual-band radio.

9. Configure dual-band transmit power for XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 txpower {tx-power-level | auto}
   ```

   Here,

   - *tx_power_level* : is the transmit power level in dBm. The range is from 1 to 8.
   - **auto** : enables auto-RF.

The XOR radio for the specified slot number is configured.

Example

```
Device> enable
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 antenna
ext-ant-gain 2
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 band 24ghz

                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 channel 3
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 cleanair
```

```
band 24Ghz
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 dot11n
antenna A
              Device# ap name AP-SIDD-A06 [no] dot11 dual-band slot 0 shutdown
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 txpower 2
```

Verify XOR radio support

To verify the XOR radio support parameters, use these **show** commands:

Verify auto-RF information

To display the auto-RF information for a Cisco AP, use the **show ap name** *ap-name* **auto-rf dot11 dual-band** command.

```
Device# show ap name cisco-ap-name auto-rf dot11 dual-band
```

Verify the list of BSSIDs

To display the list of BSSIDs for a Cisco AP, use the **show ap name** *ap-name* **wlan dot11 dual-band** command.

Receiver only dual-band radio support

Explains the features, functions, and operational constraints of receiver only dual-band radios in WLAN deployments.

A receiver only dual-band radio is a WLAN radio type that

- configures the dual-band Rx-only radio features for an AP with dual-band radios
- serves dedicated functions such as analytics, hyperlocation, wireless security monitoring, and BLE Angle of Arrival (AoA), and
- continually remains in monitor mode, preventing any *tx-rx* configuration for client or data traffic.

Enable CleanAir with receiver Only dual-band radio on a Cisco AP (GUI)

Enable CleanAir with Receiver Only Dual-Band Radio on a Cisco Access Point using GUI.

Enable CleanAir functionality on a Cisco AP that is configured with a receiver only dual-band radio through the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Dual-Band Radios** settings, click the AP for which you want to configure the dual-band radios.
3. In the **General** tab, enable the **CleanAir** toggle button.
4. Click **Update & Apply to Device**.

Enabling CleanAir with receiver only dual-band radio on a Cisco AP (CLI)

Enable CleanAir with receiver only dual-band radio on a Cisco AP using commands.

Enable CleanAir spectrum analysis for a dual-band receiver-only radio on a specified Cisco AP.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enable CleanAir with receiver only (Rx-only) dual-band radio on a specific AP.

   Example

   ```
   Device# ap name AP-SIDD-A06 dot11 rx-dual-band slot 2 cleanair band 24Ghz
   ```

   ```
   Device# ap name AP-SIDD-A06 [no] dot11 rx-dual-band slot 2 cleanair band 24Ghz
   ```

   Here, 2 refers to the slot ID. Use the ***no*** form of this command to disable CleanAir.

Disable receiver only dual-band radio on a Cisco AP (GUI)

Disable receiver only dual-band radio on a Cisco AP using GUI.

Prevent the AP from operating a receiver-only dual-band radio by using the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Dual-Band Radios** settings, click the AP for which you want to configure the dual-band radios.
3. In the **General** tab, disable the **CleanAir Status** toggle button.
4. Click **Update & Apply to Device**.

Disable receiver only dual-band radio on a Cisco AP (CLI)

Disable receiver only dual-band radio on a Cisco AP using commands.

Disable the receiver only dual-band radio function on a specific Cisco AP using commands.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Disable receiver only dual-band radio on a specific Cisco AP.

Example

```
Device# ap name AP-SIDD-A06 dot11 rx-dual-band slot 2 shutdown
```

```
Device# ap name AP-SIDD-A06 [no] dot11 rx-dual-band slot 2 shutdown
```

Here, 2 refers to the slot ID. Use the ***no*** form of this command to enable receiver only dual-band radio.

Configure client steering (CLI)

Configure client steering using commands.

Enable and customize client steering on a wireless device to optimize client distribution between macro (5 GHz) and micro (2.4 GHz) radios, improving wireless network performance and load balancing.

Before you begin
Enable Cisco CleanAir on the corresponding dual-band radio.

Procedure

1. Configure the macro-micro client load-balancing window for a set number of clients.

   Example

   ```
   Device(config)# wireless macro-micro steering transition-threshold
   balancing-window number-of-clients(0-65535) 10
   ```

2. Configure the macro-micro client parameters for a minimum client count for transition.

   Example

   ```
   Device(config)# wireless macro-micro steering transition-threshold client
   count number-of-clients(0-65535) 10
   ```

3. Configure the macro-to-micro transition RSSI.

   Example

   ```
   Device(config)# wireless macro-micro steering transition-threshold
   macro-to-micro RSSI-in-dBm( -128—0) -100
   ```

4. Configure the micro-to-macro transition RSSI.

   Example

   ```
   Device(config)# wireless macro-micro steering transition-threshold
   micro-to-macro RSSI-in-dBm(-128—0) -110
   ```

5. Configure the number of probe cycles to be suppressed.

Example

```
Device(config)# wireless macro-micro steering probe-suppression aggressiveness
 number-of-cycles(-128—0) -110
```

6. Configure the macro-to-micro probe in RSSI.

   Example

   ```
   Device(config)# wireless macro-micro steering probe-suppression hysteresis
   RSSI-in-dBm -5
   ```

   The range is between -6 to -3.

7. Enable probe suppression mode.

   Example

   ```
   Device(config)# wireless macro-micro steering probe-suppression probe-only
   ```

8. Enable probe and single authentication suppression mode.

   Example

   ```
   Device(config)# wireless macro-micro steering probe-suppression probe-auth
   ```

9. Display the wireless client steering information.

   Example

   ```
   Device# show wireless client steering
   ```

Verify Cisco APs with dual-band radios

Verify Cisco APs with dual-band radios.

To verify the APs with dual-band radios, use the command:

```
Device# show ap dot11 dual-band summary

AP Name Subband Radio      Mac   Status Channel Power Level Slot ID Mode
-------------------------------------------------------------------------
4800   All 3890.a5e6.f360 Enabled (40)* *1/8     (22 dBm)      0   Sensor
4800   All 3890.a5e6.f360 Enabled N/A    N/A       2               Monitor
```

OFDMA support for 802.11ax APs

Explains the features, functions, and operational constraints of receiver only dual-band radios in WLAN deployments.

OFDMA support for 802.11ax (Wi-Fi 6) APs is a set of wireless networking capabilities that

- improves performance in dense deployments using both 2.4 GHz and 5 GHz bands

- enables simultaneous data transmissions with technologies such as Orthogonal Frequency-Division Multiple Access (OFDMA) and MU-MIMO (Multi-User, Multiple-Input, Multiple-Output), and
- supports uplink and downlink multi-user operations across multiple client devices.

Cisco Catalyst 9100 series APs support IEEE 802.11ax and are recommended for high-performance environments.

The OFDMA mechanism ensures all users transmit or receive in synchronized time windows, ending simultaneously. This coordination supports independent data streams on the same radio frequencies for increased efficiency.

Feature history

Table 43: Feature history for OFDMA support for 802.11ax APs

Feature Name	Release Information	Feature Description
OFDMA support for 802.11ax APs	Cisco IOS XE 16.12.1	This feature enhances wireless network efficiency and user experience in high-density environments by enabling simultaneous multi-user transmissions with OFDMA and MU-MIMO across both 2.4 GHz and 5 GHz bands.

Supported modes on 802.11ax APs

802.11ax APs supported modes details.

The following AP modes are supported:

- Local mode
- FlexConnect mode
- Bridge mode
- FlexConnect+Mesh mode

Configure 802.11AX (GUI)

Configure 11AX using GUI.

Enable 802.11ax features for 5 GHz and 2.4 GHz frequency bands to optimize high throughput wireless performance.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **High Throughput**.
2. Click the **5 GHz Band** tab.
   a) Expand the **11ax** section.
   b) Check the **Enable 11ax** and **Multiple Bssid** check boxes, if required.
   c) Check either the **Select All** check box to configure all the data rates or select the desired options from the available data rates list.
3. Click the **2.4 GHz Band** tab.
   a) Expand the **11ax** section.
   b) Check the **Enable 11ax** and **Multiple Bssid** check boxes, if required.

c) Check either the **Select All** check box to configure all the data rates or select the desired options from the available data rates list.

Configure channel width (CLI)

Configure channel width with commands.

Set the 802.11 radio channel width for wireless performance tuning

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure channel width for 802.11 radios as 160.

   Example

   ```
   Device(config)# ap dot11 { 24ghz | 5ghz} rrm channel dca chan-width 160
   ```

   Use the **no** form of the command to disable the configuration.

   > **Note**
   >
   > Cisco Catalyst 9115 and C9120 series APs do not support 80+80 channel width. Cisco Catalyst 9117 series APs do not support OFDMA in 160 channel width.

3. Configure an RF profile and enters RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 { 24ghz | 5ghz} rf-profile ax-profile
   ```

4. Configure the RF profile DCA channel width.

   Example

   ```
   Device(config-rf-profile)# channel chan-width 160
   ```

Configure 802.11ax radio parameters (GUI)

Configure 802.11ax Radio Parameters using GUI.

Configure high throughput settings and 802.11ax (Wi-Fi 6) radio parameters for the 2.4 GHz and 5 GHz bands on APs using the GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **High Throughput** > **5 GHz Band** > **11ax**.
2. Check or uncheck the **Enable 11 n** check box.
3. Check the check boxes for the desired MCS/(data rate) or to select all of them, check the **Select All** check box. Click **Apply**.
4. Choose **Configuration** > **Radio Configurations** > **High Throughput** > **2.4 GHz Band** > **11ax**.
5. Check or uncheck the **Enable 11 n** check box.
6. Check the check boxes for the desired MCS/(data rate) or to select all of them, check the **Select All** check box. Click **Apply**.
7. Choose **Configuration** > **Wireless** > **Access Points**. Click the Access Point.
8. In the **Edit AP** dialog box, enable the **LED State** toggle button and select the LED brightness level from the **LED Brightness Level** drop-down list.
9. Click **Update & Apply to Device**.

Configure 802.11ax radio parameters (CLI)

Configure 802.11ax radio parameters using commands.

Set up and manage 802.11ax radio parameters on your Cisco device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the 802.11 6 GHz dot11ax parameters.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz |6ghz} dot11ax
   ```

   Use the **no** form of the command to disable the configuration.

3. Enable the 802.11ax 2.4-Ghz, 5-Ghz, or 6-Ghz band modulation and coding scheme (MCS) transmission rates.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} dot11ax mcs tx index 11
   spatial-stream 8
   ```

4. Optional: Configure the led brightness level.

Example

```
Device(config)# ap led-brightness 6
```

Set up the 802.11ax radio parameters (CLI)

Set up the 802.11ax radio parameters using commands.

Configure advanced wireless radio settings to optimize performance and coverage on Cisco APs supporting 802.11ax.

Procedure

1. Enter the privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Configure the led brightness level.

   Example

   ```
   Device# ap name ax-ap led-brightness-level 6
   ```

3. Configure the 802.11n - 5 GHz antenna selection.

   Example

   ```
   Device# ap name ap1 dot11 {24ghz | 5ghz} dot11n antenna A
   ```

   Use the **no** form of the command to disable the configuration.

4. Configure 802.11 channel width.

   Example

   ```
   Device# ap name ap1 dot11 {24ghz | 5ghz} channel width 160
   ```

5. Configure the advanced 802.11 secondary 80Mhz channel assignment parameters.

   Example

   ```
   Device# ap name ap1 dot11 {24ghz | 5ghz} secondary-80 12
   ```

Configure OFDMA on a WLAN (CLI)

Configure OFDMA on a WLAN using commands.

Enable OFDMA and related 802.11ax features on a WLAN interface.

> **Note**
>
> For Cisco Catalyst 9115 and 9120 series APs, the configuration is applied per radio, not per WLAN. The controller keeps this feature enabled if it is enabled on any WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan1
   ```

3. Enable the downlink connection that uses the OFDMA technology.

   Example

   ```
   Device(config-wlan)# dot11ax downlink-ofdma
   ```

   Use the **no** form of the command to disable the configuration.

4. Enable the uplink connection that uses the OFDMA technology.

   Example

   ```
   Device(config-wlan)# dot11ax uplink-ofdma
   ```

5. Enable the downlink connection that uses the MUMIMO technology.

   Example

   ```
   Device(config-wlan)# dot11ax downlink-mumimo
   ```

6. Enable the uplink connection that uses the MUMIMO technology.

   Example

   ```
   Device(config-wlan)# dot11ax uplink-mumimo
   ```

7. Enable the TWT broadcast support operation.

Example

```
Device (config-wlan)# dot11ax twt-broadcast-support
```

UNII-3 channels in the –E domain

UNII-3 channels in the -E domain details

UNII-3 channels are wireless frequency channels that

- operate in the -E domain with low power
- are disabled by default starting from Cisco IOS XE 17.17.1, and
- may cause coverage gaps for APs when selected by Radio Resource Management (RRM), if the client devices do not support those channels.

> **Note**
>
> Verify that your AP is listed among the Supported APs. If your AP is not listed, UNII-3 channels is disabled to meet regulatory requirements. For more information, see CSCwq22634.

Configure UNII-3 channels for –E domain (CLI)

Enable UNII-3 low-power channels for all 802.11a radios operating in the 5 GHz band in the -E domain.

Before you begin

UNII-3 low-power channels is applicable only for 5 GHz band.

Procedure

1. In global configuration mode, configure either of the following:
   a) Configure the UNII-3 channels for all 802.11a radios in the 5 GHz band for the default RF profile.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# ap dot11 5ghz rrm channel unii3-low-power-channels
   ```

   b) Configure the UNII-3 channels for all 802.11a radios in the 5 GHz band for a custom RF profile.

   Example

   ```
   Device(config)# ap dot11 5ghz rf-profile ax-profile
   ```

2. Enable UNII-3 low power channels.

Example

```
Device(config-rf-profile)# channel unii3-low-power-channels
```

3. Return to the privileged EXEC mode. Alternatively, you can also press Ctrl-Z to exit global configuration mode.

Example

```
Device(config-rf-profile)# end
```

Restrictions and supported APs

Restrictions for UNII-3 channels in the -E domain

Channel availability depends on both the configured country code and hardware certification status to guarantee lawful operation and prevent interference.

- Ensure that your configured country code is correct to guarantee legal operation and prevent interference. See CSCwd27071.
- Check whether your AP is included in the Supported APs list. If it is not, UNII-3 channels are disabled to comply with regulatory requirements. See CSCwq22634.
- If your AP is not on this list of Supported APs, UNII-3 channels are disabled or unavailable to ensure compliance with regulatory requirements.

Supported APs

- Cisco Catalyst 9136 Access Point
- Cisco Catalyst Wireless 9162I Access Point
- Cisco Catalyst Wireless 9164I Access Point
- Cisco Catalyst Wireless 9166I Access Point
- Cisco Catalyst Wireless 9178I Access Point
- Cisco Catalyst Wireless 9176I Access Point
- Cisco Catalyst Wireless 9176D1 Access Point

Verify UNII-3 channel configurations

To verify the status of the UNII-3 channel configuration in the AP RF profile details, use the command:

```
Device# show ap rf-profile name ax-profile detail

A-MPDU Window                    :  255
Zero Wait DFS                    :  Disabled
UNII-3 Low Power Channels        : Disabled
Preamble Puncturing              : Disabled
Packets Retries Settings:
Management Retries               : -1
Aggregate Retries                : -1
Non_Aggregate Retries            : -1
```

To verify the UNII-3 channel status in the 5-GHz radio configuration details, use the command:

```
Device# show ap dot11 5ghz channel

```

Note

For a 6 GHz radio, the 802.11ax parameters come from the multi BSSID profile associated with the 6 GHz RF profile of the access point. As a result, the dot11ax WLAN parameters are replaced by the parameters from the multi BSSID profile for the 6 GHz band. The 2.4 GHz and 5 GHz band WLANs do not change. These bands continue to use the WLAN parameters for 802.11ax

```
Device# show ap led-brightness-level summary

Cisco flexible antenna port

Explains the features and operating modes of Cisco flexible antenna ports used in wireless access points.

A Cisco flexible antenna port is an antenna configuration feature that

- enables APs to assign antenna ports as either single-band or dual-band
- optimizes wireless coverage and performance through flexible radio assignments, and

- supports both 2.4 GHz and 5 GHz wireless bands to accommodate various deployment scenarios.

Multiple antennas on the transmitters and receivers improve AP performance and reliability for your wireless deployment. Multiple antennas improve reception by selecting stronger signals or combining individual signals at the receiver. These mechanisms help APs deliver reliable wireless coverage. You can configure AP antenna ports as dual-band or single-band antennas to optimize radio coverage for your environment.

- In dual-band antenna mode, APs operate in both the 2.4 GHz and 5 GHz bands using all four antennas A, B, C, and D. An example of a dual-band antenna mode AP is the Cisco Industrial Wireless 3702 AP.
- In single-band antenna mode, antennas A and B operate in the 2.4 GHz band, while antennas C and D operate in the 5 GHz band. An example of a single-band antenna mode AP is the Cisco Catalyst Industrial Wireless 6300 AP.

Configure a Cisco flexible antenna port (GUI)

Configure a Cisco flexible antenna port using GUI.

Set the appropriate antenna mode on a selected AP.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click **AP Name**.
3. Click the **Advanced** tab.
4. Select the antenna mode from the **Antenna Mode** drop-down list.
5. Click **Apply & Update**.

Configure a Cisco flexible antenna port (CLI)

Configure a Cisco flexible antenna port using commands.

Set the band mode for a Cisco flexible antenna port to single or dual band using commands.

Procedure

Configure the antenna band mode as single or dual.

Example

```
Device# ap name ap-name antenna-brand-mode {dual | single}
```

Verify flexible antenna port configuration

Verify flexible antenna port configuration.

This is a sample output of the **show ap name** *ap_name* **config general** command that shows the bands selected on a specific AP:

```
Device# show ap name APXXXX.31XX.83XX config general

Cisco AP Name   : APXXXX.31XX.83XX
```

```
================================================
Cisco AP Identifier                             : b4de.312e.00c0

Environmental sensors in APs

Explains how environmental sensors in Cisco Catalyst access points enable real-time monitoring of air quality, temperature, and humidity.

Environmental sensors in APs are wireless AP features that

- enable real-time collection of environmental data such as air quality, temperature, and humidity
- embed sensors directly within supported Cisco Catalyst AP models, and
- integrate with Cisco Spaces and wireless controller CLIs to allow configuration and monitoring of sensor data.

Use the Cisco Catalyst 9800 Series Wireless Controller CLIs to enable or disable the sensors and set their scan interval.

Cisco Catalyst 9136 Series APs include two sensors:

- Total volatile organic compounds (TVOC) air quality sensor
- Combined temperature and humidity sensor

Note

Starting with Cisco IOS XE Cupertino 17.8.1, this feature is supported on Cisco Catalyst 9136 Series APs.

Cisco IOS XE Cupertino 17.9.1 adds support for air quality, temperature, and humidity on Cisco Catalyst Wireless 9166I Series Access Points.

Feature history

Table 44: Feature history for environmental sensors on APs

Feature Name	Release Information	Feature Description
Environmental sensors in APs	Cisco IOS XE 17.8.1	This feature helps you collect real-time environmental data, such as air quality, temperature, and humidity from the environmental sensors embedded in Cisco Catalyst 9136 Series APs.
Environmental sensors in APs	Cisco IOS XE 17.9.1	This feature is supported on Cisco Catalyst Wireless 9166I Series APs.

Use cases

Use cases for environmental sensors in APs.

These are the use cases for the environmental sensors in APs:

- Maintain proper storage conditions and prevent pharmaceutical spoilage in healthcare environments
- Monitor and improve air quality for guests in hospitality settings, and
- Protect perishable products from spoilage in retail spaces.

Configure environmental sensors in an AP profile (CLI)

Configure environmental sensors in an AP Profile using commands.

Enable data collection from environmental sensors in an AP profile to monitor air quality and temperature.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile.

Example

```
Device(config)# ap profile ap-profile-name
```

3. Configure the AP environmental air quality sensor.

   Example

   ```
   Device(config-ap-profile)# sensor environment air-quality
   ```

   Enters AP sensor configuration mode.

4. Enable the AP air quality sensor configuration.

   Example

   ```
   Device(config-ap-sensor)# no shutdown
   ```

5. Configure the AP environmental temperature sensor.

   Example

   ```
   Device(config-ap-profile)# sensor environment temperature
   ```

   Enters AP sensor configuration mode.

6. Enable the AP temperature sensor configuration.

   Example

   ```
   Device(config-ap-sensor)# no shutdown
   ```

7. Configure the data sampling interval, in seconds.

   Example

   ```
   Device(config-ap-sensor)# sampling data sampling interval 200
   ```

   The valid range is between five and 3600. The default value is five. Use the **no** form of this command to set the data sampling interval to the default time of five.

8. Exit the sub mode.

   Example

   ```
   Device(config-ap-sensor)# exit
   ```

Configure environment sensors (CLI)

Configure environment eensors using commands.

If an AP is sending invalid data, such as being located near an air vent or a coffee machine, disable the sensor by entering the necessary commands in the controller's privileged EXEC mode.

> **Note**
>
> A sensor operates in the **Up** state only when both the AP profile configuration state and the AP administrative state are enabled. If either state is disabled, the sensor's operational status remains **Down**.

Procedure

1. Enable the privileged EXEC mode and enter the password if prompted.

   Example

   ```
   Device> enable
   ```

2. Enable the sensor admin state of the AP.

   Example

   ```
   Device# ap name CiscoAP sensor environment {air-quality | temperature} shutdown
   ```

3. Disable the sensor admin state of the AP.

   Example

   ```
   Device# ap name CiscoAP no sensor environment {air-quality | temperature}
   shutdown
   ```

Verify the AP sensor status

Verify the AP sensor status.

To verify the status of the AP sensors, run the command:

```
Device# show ap sensor status

AP Name                          MAC-address          Sensor-type
Config-State     Admin-State     Oper-Status      Sampling-Interval

-------------------------------------------------------------------------------------------
Cisco.1DBC                        xxxx.xxxx.xxx1       Air-quality
Disabled         Enabled          Down             5
Cisco.1DBC                        xxxx.xxxx.xxx2       Temperature
Disabled         Enabled          Down             5
Cisco.1E24                        xxxx.xxxx.xxx3       Air-quality
Disabled         Enabled          Down             5
Cisco.1E24                        xxxx.xxxx.xxx4       Temperature
Disabled         Enabled          Down             5
```

Accelerometer sensor support

Accelerometer sensors allow wireless network controllers to monitor and analyze the physical installation, movement, and orientation of access points. This capability enables optimal placement, enhanced security, and improved radio frequency (RF) performance.

An accelerometer sensor is a hardware component that

- measures AP orientation and tilt using X, Y, and Z coordinates
- detects movement, misplacement, or tampering of AP, and
- enables real-time telemetry integration with wireless controllers and management platforms.

Accelerometer sensor features

- Three-axis detection: The hardware includes a three-axis accelerometer that measures X, Y, and Z coordinates and tilt angles.
- Motion and orientation monitoring: The sensor detects if an AP has been moved, tilted, or had its orientation changed.
- Real-time reporting: The sensor provides real-time data to help troubleshoot installation issues or confirm that the AP is optimally placed for radio frequency (RF) performance.
- Security and tamper detection: Sensors can identify unauthorized movement or tampering with the device.
- Telemetry integration: AP can log tilt and movement events via telemetry to the controller, Cisco Catalyst Center, or Cisco Spaces.

Supported hardware

Accelerometer sensors are available on newer enterprise-grade Cisco Catalyst and Wi-Fi 7 APs, including:

- Cisco Wireless 9174E

> **Note**
>
> CW9174E supports accelerometer only when you use the AP with CW-ANT-T-D2-D8.

- Cisco Wireless 9179F
- Cisco Wireless 9178I Series Access Points
- Cisco Wireless 9176I Series Access Points
- Cisco Wireless 9176D1
- Cisco Catalyst 9166D1 Series Access Points

Restrictions for accelerometer sensor support

This topic outlines the mandatory restrictions for enabling and deploying the accelerometer sensor feature.

- The sensor must be calibrated during the manufacturing process; manual field calibration is not supported.

Troubleshoot accelerometer sensors

This topic outlines the best practices for troubleshooting accelerometer sensors, including steps to verify access point status, enable debugging, and inspect physical installation to ensure accurate sensor readings.

If the accelerometer readings appear inaccurate, use these steps:

- Ensure the AP is fully joined to the controller and running a compatible software version.
- If data reporting issues persist, enable specific debugging for the accelerometer feature to isolate communication problems between the AP and the controller.
- Ensure the AP is securely mounted, as loose mounting brackets may cause fluctuating tilt readings.

Configure the AP accelerometer sensor (CLI)

Use this procedure to shut down or enable the environmental accelerometer sensor on an access point using CLI commands.

Manage the operational state of the accelerometer sensor to monitor or stop monitoring AP movement and orientation.

The environmental accelerometer sensor detects the physical orientation and movement of the access point. You can manually shut down this sensor if it is not required for your deployment.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Disable the environmental accelerometer sensor for a specific AP.

   Example

   ```
   Device# [no] ap name <ap-name> sensor environment accelerometer shutdown
   ```

   - Replace *<ap-name>* with the name of the AP.
   - Use the **no** form of the command to return the sensor to its operational state.

The accelerometer sensor is enabled or disabled for the specified AP as requested.

Configure accelerometer sensor at the AP join profile (CLI)

To enable the accelerometer sensor for all APs associated with a specific profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable or disable the accelerometer sensor for the profile.

Example

```
Device(config-ap-profile)# [no] ap name <ap-name> sensor environment
accelerometer
```

- Replace *<ap-name>* with the name of the AP.
- Use the **no** form of the command to return the sensor to its operational state.

The accelerometer sensor is now enabled for all APs assigned to this profile.

Verify AP sensor status and accelerometer data

This section provides information on how to verify the operational status of AP sensors and retrieve specific accelerometer data from the device and the internal database.

To ensure that AP sensors are correctly configured and operational by verifying their status, tilt angles, and database records.

Verify AP accelerometer database content

To verify AP accelerometer database content, enter this command from the console:

```
Device# show platform software process database wncd 0 chassis activ R0 details
 WNCD_DB "table tbl_ap_accelerometer" content
        Database: WNCD_DB - Table: table tbl_ap_accelerometer - Num Recs: 2
        Records

------------------------------------------------------------------------------
        422 TS:504303508759
        record@tbl_ap_accelerometer: {
        st_ap_accelerometer@st_ap_accelerometer: {
        ap_mac@tdl_mac_addr: {
        mac[0]@U8:148
        mac[1]@U8:13
        mac[2]@U8:75
        mac[3]@U8:156
        mac[4]@U8:39
        mac[5]@U8:224
        }
        last_update@calendar_time: {
        second@I64:1768515191
        microsec@U32:413575
        }
        x_coord@I16:-28
        y_coord@I16:-4
        z_coord@I16:-988
        tilt_angle@I16:1
        }
        }
```

Verify AP sensor status

To verify AP sensor status, enter this command from the console:

```
Device# show ap sensor status
        AP Name             MAC-address     Sensor-type     Config-State
Admin-State  Oper-Status  Sampling-Interval

_____________________________________________________________________________

        AP6849.92FF.A970    ecf4.0c92.ede0  Pressure        Enabled
Disabled     Down         3600
        AP6849.92FF.A970    ecf4.0c92.ede0  Accelerometer   Enabled
Enabled      Up           900
        AP8C88.8152.C6F0    940d.4b9c.27e0  Pressure        Enabled
Disabled     Down         3600
        AP8C88.8152.C6F0    940d.4b9c.27e0  Accelerometer   Enabled
Enabled      Up           900
```

Verify AP accelerometer details

To verify AP accelerometer details, enter this command from the console:

```
Device# show ap name default-ap-profile accelerometer
        Tilt angle        : 13 Degree(s)
        Last update       : 01/15/2026 22:11:47
```

To verify AP accelerometer details, enter this command from the controller:

```
Device# show ap name <ap-name> config general
        Cisco AP Name   : <ap-name>
      ================================================
      Cisco AP Identifier                     : <mac addr>
      Country Code                            : Multiple Countries : GB,IN,US

      Regulatory Domain Allowed by Country    : 802.11bg:-AE   802.11a:-ABDEN
  802.11 6GHz:-BR
      AP Country Code                         : US  - United States
      Tilt angle                              : 178 Degree(s)
```

CAPWAP LAG support

Explains how CAPWAP Link Aggregation (LAG) enables redundancy, simplifies configuration, and ensures continued connectivity between controllers and access points.

A CAPWAP LAG support feature is a controller-access point connectivity mechanism that

- enables link aggregation of controller ports.
- allows automatic failover of traffic if a port fails, and
- simplifies controller configuration by removing the requirement to configure primary and secondary ports for each interface.

Link aggregation ensures that traffic is redirected automatically to a functioning port if one controler port fails. With at least one controller port operating, network connectivity is maintained, APs stay connected and wireless clients remain operational.

CAPWAP (Control and Provisioning of Wireless Access Points) is a protocol that manages communication between wireless LAN controllers and access points.

Link Aggregation refers to using multiple network connections in parallel to increase throughput and provide redundancy.

Supported models

The CAPWAP LAG support feature applies to APs with multiple Ethernet ports for CAPWAP.

- 11AC APs with dual Ethernet ports require CAPWAP AP LAG support for their data channels.
- By default, the second port on Cisco Aironet 1850, 2800, and 3800 Series APs is used for link aggregation. If you disable LAG, you can use the LAG port as an RLAN port.

These APs use LAG port as an RLAN (Remote LAN) port:

- Cisco Aironet 1852E Access Point
- Cisco Aironet 1852I Access Point
- Cisco Aironet 2802E Access Point
- Cisco Aironet 2802I Access Point
- Cisco Aironet 3802E Access Point
- Cisco Aironet 3802I Access Point
- Cisco Aironet 3802P Access Point
- Cisco Catalyst 9136I Access Point

Note

The CAPWAP LAG feature do not support the Cisco Catalyst 9176I and Cisco Catalyst 9176D1 APs.

Restrictions for CAPWAP LAG support

CAPWAP LAG Support restrictions.

Ensure these requirements are met when using CAPWAP LAG support.

- APs must be specifically enabled for CAPWAP AP LAG support.
- CAPWAP data does not support IPv6.
- Do not enable Datagram Transport Layer Security (DTLS) when you enable LAG.
- CAPWAP LAG does not work with APs behind Network Address Translation (NAT) or Port Address Translation (PAT).

Enable CAPWAP LAG support on controller (GUI)

Enable CAPWAP LAG support on controller using GUI.

Enable LAG support for APs using the controller GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Wireless Global**.
2. Check the **AP LAG Mode** check box.

3. Click **Apply**.

Enable CAPWAP LAG support on controller (CLI)

Enable CAPWAP LAG support on controller using commands.

Enable LAG support for all APs on the controller using CAPWAP.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable CAPWAP LAG support on the controller.

   Example

   ```
   Device(config)# ap lag support
   ```

   Note

   After executing this command, this warning statement is displayed:

   Changing the lag support will cause all the APs to disconnect. Thus, all APs with LAG capability reboots and joins the enabled CAPWAP LAG.

3. Returns to privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

Enable and disable CAPWAP LAG globally on controller

Enable and disable CAPWAP LAG globally on controller.

If the CAPWAP LAG is enabled globally on the controller, these events occur:

- The AP joins the controller.
- The AP exchanges its CAPWAP support.
- LAG mode starts, if LAG is enabled on AP.

If the CAPWAP LAG is disabled globally on the controller, these events occur:

- The AP joins the controller.

- The AP exchanges its CAPWAP support.
- The AP receives the LAG configuration if LAG is already enabled on the AP.
- The AP reboots.
- The AP joins again with LAG disabled.

Enable CAPWAP LAG for an AP profile (GUI)

Enable CAPWAP LAG for an AP profile using GUI.

Enable LAG mode for a CAPWAP AP profile to improve reliability and throughput using GUI.

Procedure

1. Choose **Configuration** > **Tags (and) Profiles** > **AP Join**.
2. Click **Add**.
3. Under the **General** tab, enter the **Name** of the AP Profile and check the **LAG Mode** check box to set the CAPWAP LAG for the AP profile.
4. Click **Apply to Device**.

Enable CAPWAP LAG for an AP profile (CLI)

Enable CAPWAP LAG for an AP profile using commands.

Enable CAPWAP LAG on an AP profile to improve data throughput and provide redundancy for associated APs.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode. **ap profile** *ap-profile* .

   Example

   ```
   Device(config)# ap profile xyz-ap-profile
   ```

   Note

   When you delete a named profile, the APs associated with that profile do not revert to the default profile.

3. Enable CAPWAP LAG for an AP profile.

Example

```
Device(config-ap-profile)# lag
```

4. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Disable CAPWAP LAG for an AP profile (CLI)

Disable CAPWAP LAG for an AP profile using commands.

Disable CAPWAP LAG for a specified AP profile using commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an AP profile and enter the AP profile configuration mode.

Example

```
Device(config)# ap profile xyz-ap-profile
```

> **Note**
>
> When you delete a named profile, the APs associated with that profile do not revert to the default profile.

3. Disable CAPWAP LAG for an AP profile.

Example

```
Device(config-ap-profile)# no lag
```

4. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Disable CAPWAP LAG support on controller

Disable CAPWAP LAG support on controller using commands.

Disable LAG support for the CAPWAP protocol using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable CAPWAP LAG support on the controller .

   Example

   ```
   Device(config)# no ap lag support
   ```

   Note

   All APs with LAG capability reboots and joins the disabled CAPWAP LAG.

3. Exit configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

Verify CAPWAP LAG support configurations

Verify CAPWAP LAG support configurations.

To verify the global LAG status for all Cisco APs, use the command:

```
Device# show ap lag-mode

AP Lag-Mode Support Enabled
```

To verify the AP LAG configuration status, use the command:

```
Device# show ap name config general

Cisco AP Identifier : 0008.3291.6360
Country Code : US
Regulatory Domain Allowed by Country : 802.11bg:-A 802.11a:-AB
AP Country Code : US - United States
::
```

```
AP Lag Configuration Status : Enabled/Disabled
Has AP negotiated lag based on AP capability and per AP config
```

Configure bulk AP provisioning (GUI)

Configure bulk AP provisioning using GUI.

Use bulk AP provisioning to configure multiple parameters, such as admin status, floor location, geolocation, and high availability settings, for several APs at once.

Procedure

1. Choose **Configuration** > **Wireless** > **Bulk AP Provisioning**.

   View the current tasks and their status.

2. Click **Start a workflow to create an AP Provisioning task** to start a new bulk AP provisioning task.
3. In the **Select AP** page, configure the following:
   a) Change the name of the task.
   b) Select the APs you wish to provision.
   c) Click **Next**.
4. In the **Select Parameters** page, configure the following as required:
   a) Change the admin status using the drop-down list.
   b) Enter the location.
   c) Enter the above ground level height in meters. The range is from -100 to 1000.
   d) Enter the tolerance as uncertainty height in meters. The range is from zero to 100.
   e) Enter the cable length in meters. The range is from one to 100. The default is 10.

   > **Note**
   >
   > Keep the default value of 10 meters when using a Cisco provided external antenna. This option is available only on models that support external antennas.

   f) Enter the floor ID.
   g) Enter the name and management IP address of the primary, secondary, and tertiary controllers.
   h) Click **Next**.
5. In the **Summary** page, click **Apply** after confirming the changes.

   You can view the task status as it progresses from provisioning to completion. After selecting the task, you can view the number of configurations applied and not applied to each selected AP.

Activate tracking for deactivated infrastructure devices (GUI)

Use this procedure to initiate tracking for an inactive infrastructure device that has been deactivated. After the switch or AP becomes active, CUCM tracks its status and provides a list of endpoints that associate to the switch or AP.

Note

The controller synchronization process only adds new APs to the list and does not remove APs if they are not found.

To remove APs from the infrastructure list, mark them as inactive. After they are marked as inactive, navigate to the inactive page and delete the APs.

Because APs are stored independently in the database, controllers and APs are not directly associated. If you delete a controller, CUCM does not track AP or controller associations. APs learned from the controller stay in the system.

Before you begin

Configure Location Awareness. For more information, refer to the "Location Awareness" chapter in the *System Configuration Guide for Cisco Unified Communications Manager*.

Procedure

1. In Cisco Unified CM Administration, choose **Advanced Features** > **Device Location Tracking Services** > **Switches and Access Points**.
2. From **Related Links**, choose **Inactive Switches and Access Points** and click **Go**.
   The **Find and List Inactive Switches and Access Points** window displays the infrastructure devices that are not being tracked.
3. Select the switch or AP for which you want to initiate tracking.
4. Click **Reactivate Selected**.

CAPWAP message aggregation

Explains how CAPWAP message aggregates improve wireless network efficiency by consolidating multiple messages into a single transmission.

Control and provisioning of wireless APs message aggregation

This feature specifies details about CAPWAP message aggregation.

A CAPWAP message aggregation is a wireless communication optimization feature that

- combines multiple CAPWAP control messages of the same type into a single transmission
- temporarily stores messages in the controller when APs are busy processing packets, and
- limits the aggregated message size to the configured Maximum Transmission Unit (MTU) to maximize transmission efficiency.

Feature history
Table 45: Feature history for CAPWAP message aggregation

Feature Name	Release Information	Feature Description
CAPWAP Message Aggregation	Cisco IOS XE 17.14.1	This feature aggregates the CAPWAP control messages of the same type waiting in the queue to be transmitted to the AP.

Guidelines of CAPWAP message aggregation

Guidelines

- Applicable to all AP modes.
- The CAPWAP message aggregation feature is disabled by default.

Use cases of CAPWAP message aggregation

FlexConnect deployment

You can expect a round-trip delay when packets are sent over wide area network (WAN) in FlexConnect deployments.

- With the CAPWAP message aggregation, round-trip time decreases significantly.
- In addition, client join and roam operations complete more quickly.

Configure CAPWAP message aggregation (CLI)

The task file describes how to configure CAPWAP message aggregation in the controller console.

Enable CAPWAP message aggregation to optimize wireless network performance by reducing message overhead between APs and the controller.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Enable CAPWAP message aggregation.

   Example

   ```
   Device(config-ap-profile)# capwap aggregation
   ```

This feature is disabled by default.

4. Exit the configuration mode and return to the privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Verify CAPWAP message aggregation

The reference file describes how to verify CAPWAP message aggregation in the controller console.

To view the total number of aggregated CAPWAP control packets for the controller, use the command:

```
Device# show wireless stats ap packet

Packet stats

Capwap Control Packets Received* : 11183016
Capwap Data Keep Alive Packets Received : 160399
Capwap Data DOT1X EAP Packets Received: 549
Capwap Data DOT1X Mgmt Packets Received: 6003
Capwap Data DOT1X Key Type Packets Received: 0
Capwap Data DOT1X Control Packets Received: 0
Capwap Data ARP Packets Received: 0
Capwap Data IP Packets Received: 0
Capwap Data IPV6 Packets Received: 0
Capwap Data RRM Packets Received: 0
Capwap Data DHCP Packets Received: 0
Capwap Data RFID Packets Received: 0
Capwap Data IAPP Packets Received: 2531939
Capwap Dgram Input Errors : 0
Capwap Discovery Packets Received : 22299
Capwap Discovery Dgram Input Errors : 0
Aggregated Capwap Control Packets Sent: 119337
**** Note: Capwap control packets exclude discovery/primary discovery packets
 ****
```

To verify the status of the CAPWAP message aggregation feature, use the command:

```
Device# show ap profile name default-ap-profile detailed

AP Profile Name                : default-ap-profile
Description                    : default custom profile
Country code                   : Not configured
Stats Timer                    : 180
Link Latency                   : ENABLED
Data Encryption                : DISABLED
LED State                      : ENABLED
NTP server                     : 0.0.0.0
NTP Authentication             : DISABLED
Jumbo MTU                      : ENABLED
24ghz Report Interval          : 90
5ghz Report Interval           : 90
bssid stats status             : ENABLED
bssid stats frqncy interval    : 120
bssid neighbor stats status    : ENABLED
```

```
bssid neighbor stats interval : 120
CAPWAP Control Aggregation    : ENABLED
```

33 Secure Data Wipe

Topics:

- Secure data wipe

Secure data wipe

Explains how the secure data wipe feature on Cisco access points erases sensitive files, stores wipeout status, and assists in verification and troubleshooting.

Secure data wipe is a feature that

- securely erases files from the file system of Cisco APs using the **clear ap config** command
- stores basic information about the wipeout and its status, and
- helps verify and troubleshoot erased files.

Types of files securely erased

These files are securely erased, without possibility of recovery:

- Configuration and backup configuration files
- Crash files
- Log files
- Boot variables
- Package logs

Feature history

Feature history for secure data wipe.

Table 46: Feature history for secure data wipe

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.11.1	Secure data wipe	The Secure Data Wipe feature allows you to securely erase files from the file system of Cisco APs by using the **clear ap config** command.

Restrictions

Restrictions for secure wipe data.

Restriction for secure data wipe is as follows:

Data wipe for APs in Work Group Bridge mode can be done only through the mode button, which needs to be pressed for 20 to 60 seconds to remove storage content.

Supported AP models and software versions

Describes the supproted AP models and software versions.

Supported software versions

Cisco APs	Supported versions
Cisco Wave 1 APs	Cisco IOS XE 17.3, Cisco IOS XE 17.9.3 and its later versions, and Cisco IOS XE 17.12.
Cisco Wave 2 APs	Cisco IOS XE 17.11, Cisco IOS XE 17.12, and Cisco IOS XE 17.13.

Note

Cisco Wave 1 APs are not supported in 17.4, 17.5, 17.6, 17.7, 17.8, 17.10 and later releases.

Supported AP models

Cisco IOS APs	Cisco COS APs	Cisco Catalyst APs
3700 (I/E/P)	3800 (I/E/P)	9162I
		9164I
		9166I
		9166D1
		9163E
2700 (I/E)	2800 (I/E)	9124AX (I/D/E)
1700I	1815 (I/W)	9136I
702W	1840 (I)	9130AX (I/E)
1532I/E	1850 (I/E)	9120AX (I/E)
1570	1830 (I/W)	9117AXI
–	1810	9115AX (I/E)
–	1800I	9105AX (I/W)
–	1540	–
–	1560	–
–	4800	–

Verify data wipe

Verifies the data wipe.

To verify the output of the data wipe, run the **show flash wipeout-log** AP command:

```
Cisco-AP# show flash wipeout-log
DATA SANITATION LOGS
```

```
Filesystem Name    :    Flash
Filesystem size    :    519 M (bytes)
Total Files        :    95
Data Wipe Time     :    Fri Mar  8 09:50:49 UTC 2024
Data Wipe method   :    CLEAR
Files cleared      :    92
Bytes cleared      :    5484544 (bytes)
Total Free byte    :    458846208 (bytes)
Device PID         :    C9130AXI-E
Serial number      :    KWC233202MN
Data Wipe Status   :    SUCCESS
```

34 Wi-Fi 7 Operations

Topics:

- Wi-Fi 7 AP
- Per WLAN Wi-Fi 7 toggle

The details of the features supported by the Wi-Fi 7 APs are discussed in the following topics.

Wi-Fi 7 AP

Explains what Wi-Fi 7 APs are, their operating modes, and configurations for enterprise wireless networking.

Wi-Fi 7 APs are enterprise wireless networking devices that

- operate across tri-band frequencies (2.4 GHz, 5 GHz, and 6 GHz)
- support interoperability with 802.11ax/ac clients and hybrid deployments, and
- offer multiple radio and antenna modes for regulatory and deployment flexibility.

Cisco Wi-Fi 7 AP models

The Cisco Wireless 9176I Wi-Fi 7 AP, Cisco Wireless 9176D1 Wi-Fi 7 AP, Cisco Wireless 9178I Wi-Fi 7 AP, and Cisco Wireless 9172I Wi-Fi 7 AP, are an enterprise-class tri-band APs that operate across 2.4 GHz, 5 GHz, and 6 GHz frequencies. You can use the AP hardware with Cisco Catalyst Center, Cisco Catalyst stack, and Meraki cloud-based stack.

Operating modes and configuration

From the Cisco IOS-XE 17.15 release, split-PHY mode is supported in Cisco Wireless 9172I Series Wi-Fi 7 APs (CW9172I) radio. The radio on Cisco Wireless 9172I AP operates in the following modes:

- 5 GHz 4x4 (single-PHY)
- 5 GHz 2x2 + 6-GHz 2x2 (split-PHY)

The default mode is 5 GHz 2x2 or 6 GHz 2x2. If the AP operates in a regulatory domain where 6 GHz is not supported, it will operate in the 5 GHz 4x4 mode.

> **Note**
>
> If the AP radio power is off, then 802.11be capability of the radio is switched off. For the AP to be 802.11e capable, all radios have to be switched on.

Operating modes and configuration

From the Cisco IOS-XE 17.17 release, Cisco Wireless 9172H Series AP operates in two modes:

- 2.4 GHz(4x4) + 5 GHz(2x2) + 6 GHz(2x2)
- 2.4 GHz(4x4) + 5 GHz full band(4x4)

To access the 5 GHz full band mode(5 GHz radio in 4X4 mode):

- Configure antenna count as 4, under mapped radio profile.
- Disable the 6 GHz radio (slot 2) and reboot the AP.

If you do not reboot the AP, the 5 GHz radios will continue to operate in 2X2 mode even though the antenna count configuration is 4. The AP goes for a reboot when 6 GHz radio is enabled, as it requires a mode switch for the 6 GHz radio bring-up.

Multi-link operation (MLO)

Multi-link operation (MLO) details.

A multi-link operation (MLO) is a wireless networking feature that

- enables multi-link devices (MLDs) to maintain associations and transmit data across multiple frequency bands simultaneously including 2.4 GHz, 5 GHz, and 6 GHz bands
- integrates with the IEEE 802.11be (Wi-Fi 7) protocol to ensure dynamic network optimization, and
- adapts its functionality based on device power mode and protocol activation state.

When you enable the 802.11be (Wi-Fi 7) protocol on your device, MLO capabilities start automatically and network performance improves. If you disable the 802.11be protocol, MLO features will not be available.

Multi-link operation (MLO) modes

There are three widely adapted MLO modes.

- Multi-Link Single Radio (MLSR)
- Enhanced Multi-Link Single Radio (EMLSR)
- Multi-Link Multi Radio (MLMR)

Table 47: Feature history for multi-link operation (MLO)

Feature Name	Release Information	Feature Description
Multi-link operation (MLO)	Cisco IOS XE 17.18.1	Multi-Link Operation (MLO) is now supported even when radios are operating in low power mode. This enhancement ensures seamless multi-link operations under constrained power conditions, providing improved flexibility and efficiency for network operations. This feature is supported on the following access points only: • Cisco Wireless 9178 Series Access Points. • Cisco Wireless 9176 Series Access Points.

Feature Name	Release Information	Feature Description
Multi-link operation (MLO)	Cisco IOS XE 17.15.2	To alert users about possible disruptions, pop-up notifications or console informational messages will be displayed whenever there are changes to the radio parameters. These messages appear when the workflow is enabled or disabled, or when a radio reset occurs. The lack of support for link reconfiguration in Multi-Link Operation (MLO) may lead to client disruption during radio configuration changes. Disruption will occur for clients connected to an AP with 802.11be enabled radio, especially when 802.11be is enabled across all radio bands.

Multi-link statistics

Multi-link statistics details.

A multi-link statistics table is a data structure that

- tracks per-link and aggregated performance statistics for multi-link capable wireless clients
- uses the Multi-Link Device (MLD) client's MAC address as a key for identifying statistics, and
- maintains separate per-band statistics as clients connect to or roam between different APs and bands.

The table also provides per-band statistics for non-MLD stations. The table tracks statistics when a non-MLD station moves between bands. When a non-MLD client connects to an MLD AP, the table transfers the aggregated statistics to the per-band statistics section. When an MLD station connects to a non-MLD AP, the table preserves per-band statistics and continues accumulating aggregated statistics.

Note

In **Monitoring** > **Wireless** > **Clients** > **General** > **Clients** > **Statistics**, the display of client statistics has been updated. The statistics for Multi-Link Operation (MLO) are grouped by band instead of slot. When client statistics are recorded across multiple bands, the display shows a column for each band. Within each band, a client may be associated with one or more slots. For Non-MLO clients, the display shows aggregated data for the single band each client uses.

Configure 802.11be network parameters (CLI)

Configure 802.11be network parameters using CLI.

Set up 802.11be (Wi-Fi 7) network parameters on your device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable the 802.11b/g network, if you use 2.4 GHz, 5 GHz or 6 GHz.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} shutdown
   ```

3. Configure the 802.11be network.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} dot11be
   ```

4. Enable the 802.11b/g network, if you use 2.4 GHz, 5GHz or 6GHz.

   Example

   ```
   Device(config)# no ap dot11 {24ghz | 5ghz | 6ghz} shutdown
   ```

Configure 802.11be network parameters (GUI)

Configure 802.11be network parameters using GUI.

Set up high throughput features for your wireless network by enabling and configuring 802.11be (Wi-Fi 7) options across supported frequency bands.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **High Throughput**.
2. Click the **6 GHz Band**, **5 GHz Band** or **2.4 GHz Band** tab.
   a) Check the check box to enable **802.11be**.
   b) In the **A-MPDU Tx** section, check the check boxes to set the desired priority levels.
   c) In the **A-MSDU Tx** section, check the check boxes to set the desired priority levels.
3. Click on the **5 GHz Band** tab and in the **A-MPTDU Tx** section, and complete these:
   a) Enter the value in the field to set the **Window Size**.
   b) Toggle the button to enable the **Aggregation Scheduler**.
   c) Select either **Automatic**, **Enabled**, or **Disabled** in the **Frame Burst** drop-down list.
   d) Enter the value in the **Realtime Traffic Timeout** field. The default value is 10.
4. Click the **2.4 GHz Band** tab.
5. In the **A-MPTDU Tx** section, complete these:
   a) Enter the value in the field to set the **Window Size**.

b) Toggle the button to enable the **Aggregation Scheduler**.
c) Enter the value in the **Realtime Traffic Timeout** field. The default value is 10.

6. Click **Apply**.

Configure A-MPDU window size in RF radio profile (GUI)

Configure A-MPDU window size in RF radio profile using GUI.

Change the A-MPDU window size to optimize wireless performance for an RF radio profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.

   The **RF** window is displayed with list of profiles.

2. Click **Add**.
   The **Add RF Radio Profile** window is displayed.
3. Enter an RF profile name in the **General** tab.
4. Click the **Advanced** tab.
5. In the **A-MPDU Window Size** field enter the value.

   The valid range is between one to 255. The default value is 255.

6. Click **Apply to Device**.

Configure A-MPDU window size in RF radio profile (CLI)

Describes the CLI configuration steps for compressed block-ack window.

Set the compressed block acknowledgment (block-ack) window size for 802.11 transmit aggregated MAC protocol data units (A-MPDU) in a specific RF profile.

Procedure

1. Enter the global configuration mode.

   Example

```
Device# configure terminal
```

2. Configure an RF profile for 2.4 GHz, 5 GHz, or the 6 GHz band.

   Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rf-profile block-ack-rf-profile
```

3. Configure 802.11 transmit A-MPDU window size.

Example

```
Device(config-rf-profile)# dot11 a-mpdu tx block-ack window-size 255
```

Enable or disable client serving on AP (GUI)

Enable or disable client serving on AP using GUI.

Use this task to enable or disable client serving on an AP from the GUI.

Before you begin

Change the AP mode to **Client Serving**.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the AP name from the 6 GHz, 5 GHz, or 2.4 GHz list on the **Access Points** page.
3. Select the **Assignment Method** as *Client Serving* in the **Role Assignment** section.

   Note

   You can edit this section only if the **Assignment Method** is set to **Custom**.

4. Configure these in the **RF Channel Assignment** section:
   - Select the Channel Width from the **RF Channel Width** drop-down list.
   - Select the type of assignment from the **Assignment Method** drop-down list.

   Note

   If you choose **Custom**, you must select a channel width and specify an RF channel number to the AP radio. A 320 MHz channel width is supported from the Cisco IOS XE 17.15.1 onwards.

5. Click **Update & Apply to Device**.

Configure 802.11be MCS rates (CLI)

Describes the CLI configuration steps for 802.11be MCS rates.

Configure the modulation and coding scheme (MCS) transmission rates for 802.11be (Wi-Fi 7) APs using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the 802.11be parameters.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} dot11be
   ```

3. Enable the 802.11be 2.4 GHz, 5 GHz, or 6 GHz band modulation and coding scheme (MCS) transmission rates.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} dot11be mcs tx index {11 | 13
    | 14 | 15 | 9} spatial-stream spatial-stream-value
   ```

Configure 802.11be radio parameter frequencies (GUI)

Configure 802.11be radio parameter frequencies using GUI.

Set data rates and enable 802.11be features on supported frequency bands.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **High Throughput**.
2. Choose the **6 GHz Band** or **5 GHz Band** or **2.4 GHz Band** tab.
   a) Expand the **11be** section.
   b) Check the **Enable 11be** check box, if required.
   c) Check either the **Select All** check box to configure all the data rates or select the desired options from the available data rates list.
3. Click **Apply**.

Configure multi BSSID 802.11be parameters (GUI)

Configure multi BSSID 802.11be parameters using GUI.

Configure advanced 802.11be parameters within a multi BSSID profile to manage Orthogonal frequency-division multiple access (OFDMA) and MU-MIMO settings.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Multi BSSID**.
2. Click **Add**.

The **Add Multi BSSID Profile** window is displayed.

3. Enable or disable the following parameters in the **802.11be** section:
   - **OFDMA Downlink**
   - **OFDMA Uplink**
   - **MU-MIMO Downlink**
   - **MU-MIMO Uplink**
   - **OFDMA Multi-RU**

   Note

   OFDMA Downlink and **OFDMA Uplink** are enabled by default.

4. Click **Apply to Device**.

Configure multi BSSID 802.11be parameters (CLI)

Describes the CLI steps to configure 802.11be parameters in the multi-BSSID profile.

Note

Multi-BSSID profile configuration overwrites the 802.11be profile configuration for 6-GHz band.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the multi BSSID profile and enter the multi BSSID profile configuration.

   Example

   ```
   Device# wireless profile multi-bssid default-multi-bssid-profile
   ```

3. Configure the 802.11be parameters.

Example

```
Device# dot11be {downlink-mumimo | downlink-ofdma | ofdma-multi-ru |
uplink-mumimo | uplink-ofdma}
```

Configure 802.11be parameters (GUI)

Configure 802.11be parameters using GUI.

Modify 802.11be profile parameters to optimize wireless performance for specific user profiles.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **802.11be**.

   The different user profiles are listed.

2. Click the required profile.

   The **Edit 802.11be Profile** window is displayed.

3. Click to **Enable** or **Disable** the **OFDMA Downlink**, **OFDMA Uplink**, **MU-MIMO Downlink**, **MU-MIMO Uplink**, and **OFDMA Multi-RU** in the **Edit 802.11be Profile** window.
4. Click **Update and Apply to Device**.

Monitor 5 GHz radio WLAN slot data (GUI)

Monitor 5 GHz radio WLAN slot data using GUI.

View and confirm the WLAN ID, BSSID MAC, and MLD MAC information for APs operating on the 5 GHz radio.

Procedure

1. Choose **Monitoring** > **Wireless** > **Radio Statistics**.
2. Click the **5 GHz Radios** tab, then select the required AP.
3. Verify the **WLAN ID**, **BSSID MAC**, and **MLD MAC** in the **WLAN Slot Data** section.

   The **5 GHz Band** window is displayed.

4. Click **OK**.

Monitor 802.11be radio parameters (GUI)

Monitor 802.11be radio parameters using GUI

View and verify preamble puncturing parameters for 802.11be radios in the wireless monitoring dashboard.

Procedure

1. Choose **Monitoring** > **Wireless** > **Radio Statistics**.
2. Click the **6 GHz Radios** tab and select the required AP.

3. Verify these to monitor preamble puncturing in the **11be Parameters** section:
   a) **Puncture Reason**
   b) **Punctured Channels**
4. Click **OK**.

Verify multi-link statistics

Verify multi-link statistics details.

Verify wireless client MAC address details

To verify the wireless client mac-address mobility history, use the command:

```
Device# #show wireless client mac-address e460.17bb.3a50 mobility history

Recent association history (most recent on top):

AP Name                                       BSSID           AP Slot    Assoc
 Time               Instance   Mobility Role   Run Latency (ms)     Dot11 Roam
 Type
-------------------------------------------------------------------------------
WiFi7_AP1_2036                                c614.a26e.c218  1

default-dot11be-profile           Default 802.11be profile
```

Verify 320 MHz details (GUI)

Verify 320 MHz details using GUI.

> **Note**
>
> - 320 MHz is supported only on the 6-GHz band.
> - By default, the Dynamic Channel Assignment (DCA) maximum bandwidth is 160 MHz. Users need to enable 320 MHz in the 6-GHz RF Profile to utilize it.

Confirm that 320 MHz operation is enabled and functioning on the 6 GHz band by reviewing channel request and response data in the GUI.

Procedure

1. Choose **Monitoring** > **Wireless** > **AP Statistics**.
2. Select **General**.

   A list of APs under the **General** tab is displayed.
3. Select the required profile from the list.

   A **General** window is displayed.
4. Select **AFC** and then choose **Request**.
5. Verify the **320 MHz Channel Request Data** from the **Channel Request Data** table.
6. Select **AFC** and then choose **Response**.
7. Verify the **320 MHz Channel Response Data** from the **Channel Response Data** table.

Verify multi BSSID details

Verify multi BSSID details.

Verify multiple link device (MLD) MAC details

To display the 802.11be profile details, run the command:

```
Device# show ap name cisco-ap wlan dot11 5ghz
-------------------------------------------------------------
Slot id : 1
WLAN ID BSSID MLD
-------------------------------------------------
9 0aef.2500.010f 0aef.2501.0001
2 0aef.2500.010e 0aef.2501.0002
3 0aef.2500.010d 0aef.2501.0003
4 0aef.2500.010c 0aef.2501.0004
12 0aef.2500.010b 0aef.2501.0005
14 0aef.2500.010a 0aef.2501.0006
16 0aef.2500.0109 NA
```

Verify multi BSSID set ID and Tx VAP indicator details for 6 GHz radio

To display the 802.11be profile details, run the command:

```
Device# show ap name WSIM-AP-0001 wlan dot11 6ghz
-------------------------------------------------------------
Slot id : 3
WLAN ID BSSID MLD MBSSID Set ID
-------------------------------------------------------------------------------
9 0aef.2500.0108 0aef.2501.0001 1*
2 0aef.2500.0109 0aef.2501.0002 1
3 0aef.2500.010a 0aef.2501.0003 1
4 0aef.2500.010b 0aef.2501.0004 1
12 0aef.2500.010c 0aef.2501.0005 NA (11be WLAN not 6GHz compliant)
14 0aef.2500.010d 0aef.2501.0006 2*
16 0aef.2500.010e NA 3* (11ax 6GHz WLAN)
18 0aef.2500.010f NA NA (11ax non-6GHz WLAN)
```

Per WLAN Wi-Fi 7 toggle

Explains how Wi-Fi 7 options can be enabled or disabled per WLAN in network management platforms.

Feature history for per WLAN Wi-Fi 7 toggle

Per WLAN Wi-Fi 7 toggle feature history.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 48: Feature history for access point upgrade management enhancements

Release	Feature Information
Cisco IOS XE 17.18.1	Per-WLAN 802.11be configuration is an enhancement in WLAN configurations that provides: • WLAN level control for 802.11be (Wi-Fi 7) configurations. • The ability to enable or disable 802.11 be (Wi-Fi 7) on a per WLAN basis. • Support for running both Wi-Fi 7 and non-Wi-Fi 7 WLANs simultaneously on the same radio frequency band.

Per-WLAN 802.11be configuration

This topic describes the per-WLAN 802.11be configuration.

Per-WLAN 802.11be configuration is an enhancement in WLAN configurations.

- It introduces WLAN-level control for 802.11be configurations.
- This capability supports both 802.11be and non-802.11be WLANs in the same radio frequency band.
- The configuration offers greater flexibility compared to previous versions.

Starting with Cisco IOS XE 17.18.1 release, you can enable or disable Wi-Fi 7 (802.11be) on a per WLAN basis. This change allows you to run both Wi-Fi 7 and non-Wi-Fi 7 WLANs simultaneously on the same radio band. It offers more flexibility compared to previous releases, where Wi-Fi 7 was configured as a global radio setting.

Upon upgrading to release 17.18.1, a default 802.11be profile is automatically created. This profile enables 802.11be on all bands (2.4 GHz, 5 GHz primary and secondary, and 6 GHz). You can configure custom 802.11be profiles starting from release 17.18.1.

> ⚠ **Caution**
>
> Modifying the default 802.11be profile affects the configuration across all bands where it is enabled.

Supported WLANs

This topic describes the supported WLANs.

WLANs with below security configuration combinations can operate in Wi-Fi 7 mode:

- WPA3-SAE-EXT-KEY/WPA3-SAE-EXT-KEY-FT + WPA3-SAE/WPA3-SAE-EXT + GCMP256 + AES
- WPA3-802.1x-SHA256/WPA3-SuiteB-192 + WPA2-802.1x + AES/GCMP256
- PMF Required/Optional

> **Note**
>
> WLANs that are not compatible with Wi-Fi 7 security restrictions are automatically downgraded to the 802.11ax mode. This process ensures that these WLANs remain operational even when Wi-Fi 7 is enabled globally.

Supported security configurations for 802.11be

This topic describes the supported security configurations for 802.11be.

Table 49: Security configurations

Security combination	AKM/Cipher	PMF (802.11w required/optional)	Beacon
WPA3-OWE + GCMP256	OWE + GCMP256 + AES	Yes	MLO + EHT(11be); No OWE element
WPA3 + WPA2	• 802.1x + 802.1x-sha256 • 802.1x + suite-b-192 • 802.1x-FT + 802.1x-sha256	Yes	MLO + EHT
WPA3	• 802.1x-sha256, 802.1x-FT • Suite B - 192 Bit Security • SAE-EXT/SAE-EXT-FT + GCMP256 + AES	Yes	MLO + EHT
WPA3+WPA2	SAE/SAE-FT+H2E + AES + SAE-EXT/SAE-EXT-FT + GCMP256	Yes	MLO + EHT
WPA3 OWE Transition Mode	• OWE WLAN: OWE + GCMP256 • OWE WLAN: OWE+AES+GCMP256	Yes	MLO + EHT
Wi-Fi 7 compliant security + non-compliant security	Wi-Fi 7 compliant security + non-compliant WPA3 security	Yes	MLO + EHT
WPA3 OWE	OWE + AES/GCMP256	Yes	MLO + EHT

> **Note**
>
> OWE transition WLAN(Wi-Fi Enhanced Open Transition Mode) configuration is not supported for Wi-Fi 7(802.11be) WLANs.

Beacon-Protection status

This topic describes Beacon-Protection status.

If 802.11be is enabled and WLAN security meets the 802.11be requirement, Beacon-Protection is auto-enabled.

> **Note**
>
> Beacon-Protection is a mandatory configuration for Wi-Fi 7(802.11be) WLANs.

MBSSID

MBSSID SET-ID

This topic describes the MBSSID SET-ID.

WLANs are arranged into compatible MBSSID (Multiple Basic Service Set Identifier) sets. The placement of each WLAN in an MBSSID set determines the VAP ID or BSSID MAC address. The 6-GHz band supports up to 16 WLANs. Therefore, four MBSSID sets with four WLANs in each group is automatically created. In each group, one WLAN is the Tx-VAP and the other three are non-Tx-VAP.

The grouping is done based on 802.11be against 802.11ax profile WLANs and whether it is a GCMP-128 against GCMP-256 cipher WLAN.

MBSSID grouping for 802.11be and non 802.11be deployments

This topic describes MBSSID grouping for 802.11be and non 802.11be deployments.

MBSSID grouping for non 802.11be deployments:

The configuration options when grouping WLANs into an MBSSID set are:

- 6 GHz policy (applicable or not applicable).
- Beacon protection state.
- Configure the cipher to use either 128-bit or 256-bit encryption when beacon protection is enabled.

MBSSID grouping for 802.11be deployments:

The configuration options when grouping WLANs into an MBSSID set are:

- 6 GHz policy (applicable or not applicable).
- The PHY mode for the 6 GHz slot in the corresponding 802.11be profile is either 802.11be or 802.11ax.
- Configure the cipher to use either 128-bit or 256-bit encryption.

> **Note**
>
> Beacon-protection is enabled for 802.11be deployments.

Disabled - no MBSSID slot

This topic describes the disabled - no MBSSID slot.

The WLAN is disabled in the 6 GHz band because there is no available MBSSID slot to accommodate it. This occurs due to MBSSID limitations or conflicting configurations. If the controller fails to map a WLAN into any of the four groups, it is marked as Disabled on the 6 GHz band by the system.

> **Note**
>
> This change does not affect the 2.4 GHz or 5 GHz bands.

Tx-VAP WLAN of MBSSID set for 6 GHz band

This topic describes Tx-VAP WLAN of MBSSID set for 6 GHz band.

The VAP within an MBSSID set transmits beacon frames for the group. In 802.11ax and 802.11be networks, multiple WLANs can be grouped into an MBSSID set to increase efficiency. The Tx-VAP sends beacon frames for the entire set. An asterisk (*) identifies the VAP that transmits beacon frames for the group.

The WLAN per-link configuration determines the VAP mode when 802.11be is enabled at the radio band level.

These conditions confirm the BSSID type as 802.11be or non 802.11be:

- If 802.11be is enabled at both the band and WLAN levels, the BSSID is 802.11be.
- If 802.11be is enabled at the band level but disabled at the WLAN level, the BSSID is non-802.11be.
- If 802.11be is disabled at the band level, all BSSIDs on that radio are non-802.11be, regardless of the WLAN per-link configuration.

Create a new 802.11be profile (GUI)

This topic describes how to create a new 802.11be profile using GUI.

Create a new 802.11be profile to to enable Wi-Fi 7 (802.11be) configuration using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **802.11be**.
2. Click **Add**.
3. In the **Add 802.11be Profile** page, add the **Profile Name** and **Description**.
4. In the **MLO group** section, use the toggle button to either enable or disable the **Primary 2.4GHz**, **Primary 5GHz**, **Secondary 5GHz** and **Primary 6GHz** bands.
5. Click **Apply to Device**.

Map the 802.11be profile to a WLAN (GUI)

This topic describes how to map the 802.11be profile to a WLAN using GUI.

Map the new 802.11be profile to a specific WLAN.

Procedure

1. Choose **Configuration** > **Tags and Profiles** > **WLANs**.
2. Select the WLAN and click the **Advanced** tab.
   The **Advanced** tab is displayed.
3. Scroll down to the **11be** section.
4. From the **802.11be Profile** drop-down list, select the required WLAN.
5. Click **Update & Apply to Device**.

Create and map 802.11be profile (CLI)

This topic describes how to create and map 802.11be profile using the CLI.

Create a 802.11be profile using the CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure and name the wireless 802.11be profile.

   Example

   ```
   Device(config)# wireless profile dot11be 802.11be-prof-name
   ```

3. Configure MLO group settings for each radio link.

   Example

   ```
   Device(config-wireless-dot11be-profile)# mlo-group {24ghz | 5ghz | 5ghz-sec
   | 6ghz}
   ```

   The options are:

   - **24ghz**: Enable 2.4 GHz in MLO group.
   - **5ghz**: Enable 5 GHz in MLO group.
   - **5ghz-sec**: Enable secondary 5 GHz in MLO group.
   - **6ghz**: Enable 6 GHz in MLO group.

> **Note**
>
> Use the **no** form of this command to disable MLO group settings for each radio link, that is for 2.4 GHz, 5 GHz, secondary 5 GHz, and 6 GHz radio links, respectively.
>
> ```
> Device(config-wireless-dot11be-profile)# mlo-group {no-24ghz | no-5ghz  |
>  no-5ghz-sec | no-6ghz}
> ```

4. Exit to global configuration mode.

   Example

   ```
   Device(config-wireless-dot11be-profile)# exit
   ```

Map the 802.11be Profile to a WLAN

Map the 802.11be profile using the CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile.

   Example

   ```
   Device(config)# wlan wlan-profile-name
   ```

   This command configures the WLAN profile and enters the WLAN configuration mode.

3. Disable the WLAN profile.

   Example

   ```
   Device(config-wlan)# shutdown
   ```

4. Configure 802.11be profile for this WLAN.

   Example

   ```
   Device(config-wlan)# [no] dot11be-profile dot11be-prof-name
   ```

   Use the **no** form of this command to disable this feature.

Verify 802.11be profile details

This topic describes how to verify 802.11be profile details.

To verify 802.11be profile details, run the **show wireless profile dot11be summary** command.

```
Device# show wireless profile dot11be summary
Number of dot11be profiles: 7

Dot11be profile name              Description
------------------------------------------------------------------------
6ghz@disable@11be                 disabling 11be on 6ghz band
24ghz_disable_11be                disabling 11be on 2.4GHz band

Verify 802.11be profile parameters with MLO mapping

This topic describes how to verify 802.11be profile parameters with MLO mapping.

To verify 802.11be profile parameters with MLO mapping, run the **show wireless profile dot11be detailed** *11be-prof-name* and **show wireless profile dot11be detailed***24ghz_disable_ 11be* commands.

```
Device# show wireless profile dot11be detailed 11be-prof-name
Device# show wireless profile dot11be detailed 24ghz_disable_11be

Dot11be profile name           : 24ghz_disable_11be
-------------------------------------------------
Description                    : disabling 11be on 2.4GHz band
802.11be parameters
    OFDMA Downlink             : Enabled
    OFDMA Uplink               : Enabled
    MU-MIMO Downlink           : Enabled
    MU-MIMO Uplink             : Enabled
    OFDMA Multi-RU             : Enabled
MLO Group
    24ghz link                 : Disabled
    5ghz link                  : Enabled
    5ghz secondary link        : Enabled
    6ghz link                  : Enabled
```

Verify 802.11be profile mapping to WLAN

This topic describes how to verify 802.11be profile mapping to WLAN.

To verify 802.11be profile mapping to WLAN, run the **show wireless profile dot11be detailed** *6ghz@disable@11be* command.

```
Device# show wireless profile dot11be detailed 6ghz@disable@11be
Dot11be profile name           : 6ghz@disable@11be
-------------------------------------------------
Description                    : disabling 11be on 6ghz band
802.11be parameters
    OFDMA Multi-RU             : Enabled
MLO Group
    24ghz link                 : Enabled
```

```
    5ghz link                  : Enabled
    5ghz secondary link        : Enabled
    6ghz link                  : Disabled
```

Verify VAP status for 802.11ax and 802.11be WLAN on 6 GHz band

This topic describes how to verify VAP status for 802.11ax and 802.11be WLAN on 6 GHz band.

To verify VAP status for 802.11ax and 802.11be WLAN on 6 GHz band, run the **show wireless tag policy detailed** *11ax-prof-name-policy-tag* **vap-id** command.

This table refers the MBBSID grouping for a 802.11ax AP (non 802.11be deployment).

```
Device #show wireless tag policy detailed 11ax-prof-name-policy-tag vap-id

WLAN-ID  WLAN profile name                  Policy profile name
VAP-ID  status    SET-ID  Beacon-Protection status  operational state
-------------------------------------------------------------------------------------------
1            open                          default-policy-profile            2
      Enabled   1*      Enabled (128bit cipher)   Enabled
4        wpa3sae                           policy-profile             1
  Enabled   1       Enabled (128bit cipher)   Enabled
5        wpa3owe                           policy-profile             3
  Enabled   1       Disabled                  Enabled
15       mbssid-1                          policy-profile             4
  Enabled   1       Disabled                  Enabled
12       mbssid-8                          default-policy-profile

-------------------------------------------------------------------------------------------
16385    rlan_profile               rlan*policy                1        16
```

Note

***** refers to Tx-VAP WLAN of MBSSID set and 0 refers to invalid MBSSID set-id. WLAN is not broadcast in the 6-GHz band.

Verify Policy Tag for 802.11be WLAN VAP Status on 6 GHz

To verify Policy Tag detail view to check the VAP status for 802.11be WLAN status on 6 GHz band, run the **show wireless tag policy detailed** *11be-prof-name-policy-tag* **vap-id** command.

This table refers to the MBBSID grouping for a 802.11be AP (802.11be deployment). The WLANs downgraded to 802.11ax do not adhere to the 802.11be security standards. The WLAN with no MBSSID slot is not shown in the 6 GHz but only in the 2.4 GHz & 5 GHz.

```
Device #show wireless tag policy detailed 11be-prof-name-policy-tag vap-id

              |-------------------------------------------------------------|

                |                        6GHz VAP information

16385    rlan_profile                rlan*policy                1        12
```

Note

***** refers to Tx-VAP WLAN of MBSSID set and 0 refers to invalid MBSSID set-id. WLAN is not broadcast in the 6-GHz band. The first six WLANs are degraded to 802.11ax.

Verify WLAN downgrade from 802.11be to 802.11ax mode

This topic describes how to verify WLAN downgrade from 802.11be to 802.11ax mode.

To verify WLAN downgrade from 802.11be to 802.11ax mode, run the **show ap wlan summary** command.

This table describes the reason for downgrading the WLAN.

```
Device# show ap wlan summary

ecf4.0caf.23e1  wpa3owe                           wpa3owe

Verify AP WLAN information on 6 GHz band with MBSSID slot

This topic describes how to verify AP WLAN information on 6 GHz band with MBSSID slot.

To verify AP WLAN information on 6 GHz band with MBSSID slot, run the **show ap name***row-AP-11be***wlan dot11 6ghz** command.

```
Device# show ap name row-AP-11be wlan dot11 6ghz

Slot id  : 2
  * Tx-VAP WLAN of MBSSID set
  WLAN ID    BSSID          MLD MAC                MBSSID SET ID

35 Troubleshooting Lightweight Access Points

Topics:

- Support resources for technical issue resolution

Support resources for technical issue resolution

Lists the available support resources, escalation guidance, and recommendations for resolving technical problems efficiently.

These resources help you resolve problems quickly and provide guidance if you need to escalate the issue.

We offer a variety of SME-authored support documents to help you resolve technical issues without opening a support ticket.

- You can access curated documents written by Cisco SMEs for common technical concerns.
- If a document resolves your issue, no support ticket is required.
- If you need additional help, visit the Cisco Community for solutions provided by other Cisco users. You can find information and advice from Cisco customers who have had similar issues and shared their solutions.
- If your issue persists, open a support ticket at Cisco Support.

> **Note**
>
> When you need to open a support ticket, these documents explain what information you should collect and include in your request. Specify the support document you consulted, and TAC can create an improvement request with the document owner.

Support articles

This section includes documents with use cases that explain why a tunnel break occurs between the Wireless Controller and the APs.

You can apply these documents to different software and hardware listed in the **Components Used** section of each article. However, this does not mean these documents are limited to the items listed in **Components Used**, even if the listed components are for earlier releases.

- Be aware that changes in software or hardware may affect commands to stop working, syntax to change, or GUIs and CLIs to look different between releases.
- The Troubleshoot Access Point Disassociation from Controller explains why a Control and Provisioning of Wireless Access Points (CAPWAP) or Lightweight Access Point Protocol (LWAPP) tunnel may break between Access Points (APs) and the Wireless Controller.

Provide feedback on support documents

You can help improve Cisco support documents by submitting feedback.

Your input helps. A key aspect to improving these support documents is customer feedback. Note that multiple teams maintain and update these documents within Cisco. If you find an issue specific to the document, such as unclear information, confusing sections, or missing information

- provide feedback using the **Feedback** button located in the right panel of the article. The document owner is notified and will either update the article or flag it for removal, and
- include information about the section, area, or issue you had with the document, and suggest what could be improved. Provide detailed information to help us understand your feedback.

Disclaimer and caution

Read this disclaimer and caution about default device configurations so you understand the potential impact of any command.

The information in this document is based on tests performed in a specific lab environment.

- All devices in the lab started with a cleared (default) configuration.
- If you are working on a live network, understand the potential impact of each command before you use it.

Part IV

Access Points Modes

Topics:

- Sniffer Mode
- Monitor Mode
- Management Mode Migration in Cisco Catalyst 916X Access Points
- Configure the controller for FlexConnect
- OEAP Link Test
- Cisco OEAP Split Tunneling
- Access Points Survey Mode
- AP Deployment Mode

36 Sniffer Mode

Topics:

- Sniffer

Sniffer

Introduces sniffer mode concepts for access points, covering XOR radio role sniffer support, prerequisites, restrictions, GUI and CLI configuration, enabling or disabling sniffer functionality, monitoring, XOR radio configuration tasks, and verification with practical examples for effective deployment and troubleshooting.

A sniffer is a network monitoring tool that

- captures and forwards packets on a specified channel to a remote packet analyzer
- allows monitoring and recording of network activity
- detects network problems, and
- receives encapsulated 802.11 traffic at the packet analyzer.

Key characteristics

- Network packet capture: The sniffer captures live packets and forwards them to a packet analyzer for inspection.
- Protocol support: It works with protocols like Airopeek for encapsulation and transfer via specified UDP ports.
- Management integration: Sniffers can be configured through AP modes and require resetting to revert to normal operations.

Recommendations

- Use **Clear** in AP mode to return the AP back to client-serving mode, such as local or FlexConnect depending on the remote site tag configuration.
- Do not use the AP command to change the CAPWAP mode.

XOR radio roles

XOR Radio Role Sniffer support details.

A XOR radio is a configuration that

- allows the XOR radio to function in multiple modes via a single radio interface
- eliminates the need to switch the entire AP into a separate mode, and
- is implemented at the radio level and referred to as "roles."

XOR radio roles facilitate the operation of wireless network radios. This is specifically applicable to models like the Cisco Catalyst 2800, 3800, 4800, and 9100 series AP models. The Sniffer role, supported from the current release onwards, is offered alongside the Client Serving and Monitor roles.

Feature history for sniffer mode
Table 50: Feature history

Release	Feature	Feature information
Cisco IOS XE 17.8.1	XOR Radio Role Sniffer Support on the Access Point	The XOR radio in APs like Cisco 2800, 3800, 4800, and the 9100 series AP models support sniffer role in single radio interface.

Supporting reference information

The radio role is supported in both Local and FlexConnect modes.

Essential hardware and software for sniffer setup

Sniffer prerequisites.

- A dedicated access point: An AP configured as a sniffer cannot simultaneously provide wireless access service on the network. To avoid disrupting coverage, use an access point that is not part of your existing wireless network.
- A remote monitoring device: A computer capable of running the analyzer software.
- Software, supporting files, plug-ins, or adapters: Your analyzer software may require specialized files to function effectively.

Restrictions on sniffer

Sniffer restrictions.

- These are the supported third-party network analyzer software applications:
  - Wildpackets Omnipeek or Airopeek
  - AirMagnet Enterprise Analyzer
  - Wireshark
- The latest version of Wireshark can decode the packets by going to the Analyze mode. Select **decode as**, and switch UDP5555 to decode as PEEKREMOTE.
- You cannot use Sniffer mode when the controller L3 interface is the Wireless Management Interface (WMI).
- When an AP or a radio operates in the sniffer mode, irrespective of its current channel width settings, the AP sniffs or captures only on the primary channel.
- Avoid enabling AP sniffer mode when the controller is connected to Cisco Application Centric Infrastructure (ACI) that uses default endpoint learning. For more information, refer to CSCwa45713.

> **Note**
>
> As both Cisco Catalyst 9166I and 9166D APs have XOR radios, a Board Device File (BDF) has to be loaded to initialize radio 2 for the radios of these APs to work as expected. While the BDF is being loaded and for the file to be loaded correctly, the firmware has to be made non-operational and radios have to be reset. This operation of radio reset due to firmware being non-operational for the purposes of loading the BDFs is deliberate and is an expected behavior. This operation can be observed in both the controller and Cisco Catalyst Center. We recommend that you ignore the core dump that is generated due to this deliberate operation.

Configure an access point as sniffer (GUI)

Configure an access point as sniffer using GUI.

This task guides you through configuring an access point to sniffer mode using the GUI, allowing the access point to capture wireless traffic in a specified location.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **General** tab, update the name of the AP. The AP name can be ASCII characters from 33 to 126, without leading and trailing spaces.
3. Specify the physical location where the AP is present.
4. Choose the **Admin Status** as **Enabled** if the AP is to be in enabled state.
5. Choose the mode for the AP as *Sniffer*.
6. In the **Tags** section, specify the appropriate policy, site, and RF tags that you created on the **Configuration** > **Tags & Profiles** > **Tags** page.

   Note

   If the AP is in sniffer mode, you do not want to assign any tag.

7. Click **Update & Apply to Device**.
8. Choose the mode for the AP as **Clear** to return the AP back to the client-serving mode depending on the remote site tag configuration.

   Note

   Changing the AP mode to Sniffer will set all radios to manual mode. A warning prompts you to revert the radio submode to AUTO if required when changing modes.

The AP is configured in sniffer mode, ready for capturing wireless traffic at the specified location.

Configure an access point as sniffer (CLI)

Configure an access point as sniffer using commands.

Set an AP to sniffer mode so that it can monitor network traffic.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device>enable
   ```

2. Configure the AP to function as a sniffer.

Example

```
Device# ap name access1 mode sniffer
```

Where,

- *ap-name* is the name of the Cisco lightweight access point.
- Use the **no** form of this command to disable the access point as a sniffer.

The AP operates in sniffer mode, capturing and monitoring network traffic.

Enable or disable sniffing on the AP (GUI)

Use the GUI to enable or disable sniffing on the access point.

This task guides you through enabling or disabling sniffing mode on an AP using the GUI.

Before you begin

You must change the AP mode to sniffer mode.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **Access Points** page, click the AP name from the 6 GHz, 5 GHz, or 2.4 GHz list.
3. In the **Role Assignment** section, select the **Assignment Method** as *Sniffer*.
4. In the **Sniffer Channel Assignment** section, check the **Sniffer Channel Assignment** checkbox to enable.

   Uncheck the checkbox to disable sniffing on the access point.
5. From the **Sniff Channel** drop-down list, select the channel.

   Note

   By default, the **Sniff Channel** is set to *36* for the **5 GHz** and *1* for the **2.4 GHz**.
6. Enter the IP address into the **Sniffer IP** field.

   To validate the IP address, click **Update & Apply to Device**. If the IP address is valid, the **Sniffer IP Status** displays *Valid*.
7. **Note**

   The section will be enabled for editing only if the **Assignment Method** is set to **Custom**.

   In the **RF Channel Assignment** section, configure these items:

   - From the **RF Channel Width** drop-down list, select the channel width.

- From the **Assignment Method** drop-down list, choose the type of assignment.

> **Note**
>
> If you choose Custom, you must select a channel width and specify an RF channel number to the access point radio. 320 MHz channel width is supported from Cisco IOS XE 17.15.1 onwards.

8. Click **Update & Apply to Device**.

The AP is configured to either operate in sniffing mode or have sniffing mode disabled based on your choice.

Enable or disable sniffing on the AP (CLI)

Enable or Disable Sniffing on the Access Point using commands.

This task enables you to manage the sniffing feature on an AP using CLI commands, specifically to enable or disable it as necessary.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Enable sniffing on the AP.

   Example

   ```
   Device# <userinput>ap name access1 sniff dot11b 1 9.9.48.5</userinput>
   ```

   - *channel* is the valid channel to be sniffed. For 802.11a, the range is 36 to 165. For 802.11b, the range is 1 to 14. For dot11 6 GHz, the range is between 1 and 233.
   - *server-ip* is the IP address of the machine running network monitoring software.

3. Disable sniffing on the AP.

   Example

   ```
   Device#<userinput>ap name access1 no sniff dot116ghz</userinput>
   ```

The sniffing feature is enabled or disabled on the AP based on the commands executed. Ensure that you verify the current status of the configuration.

Configure XOR radio role sniffer support on the access point (CLI)

Configure XOR radio role sniffer support on access points using commands.

Enable the XOR radio on a AP to operate as a sniffer by manually configuring its role and settings through CLI.

Procedure

1. Enable privileged EXEC mode. Enter your password, if prompted.

   Example

   ```
   Device> enable
   ```

2. Shut down the XOR radio.

   Example

   ```
   Device# ap name AP687D.B45C.189C dot11 dual-band shutdown
   ```

3. Convert the XOR radio role to manual.

   Example

   ```
   Device# ap name ap-name dot11 dual-band role manual client-serving
   ```

4. Configure XOR radio to manually operate in a specific band.

   Example

   ```
   Device# ap name  AP687D.B45C.189C dot11 dual-band band 5ghz
   ```

5. Enable XOR radio role Sniffer support on AP from the controller.

   Example

   ```
   Device# ap name AP687D.B45C.189C dot11 dual-band radio role manual sniffer
   channel 100 ip 9.4.197.85
   ```

   Where,

   - *ap-name* is the name of the Cisco lightweight access point.
   - *channel-number* is the channel number.

6. Activate the XOR radio.

   Example

   ```
   Device# ap name AP687D.B45C.189C no dot11 dual-band shutdown
   ```

7. Return to privileged EXEC mode.

Example

```
Device# end
```

Note

When configuring the radio to work as a Sniffer in the 5 GHz band, make sure to change the band of the radio manually.

XOR radio on the AP is configured to operate as a sniffer, allowing you to monitor and analyze wireless traffic on a specified channel.

Verify sniffer configurations

Verify Sniffer configurations.

Use these commands to verify sniffer configurations on AP and gather specifics regarding the sniffing setup in multiple bands and slots.

Table 51: Commands for verifying sniffer configurations

Commands	Description
show ap name *ap-name* **config dot11 {24ghz | 5ghz | 6ghz | dual-band}**	Displays the sniffing details.
show ap name *ap-name* **config slot** *slot-ID*	Displays the sniffing configuration details. *slot-ID* ranges from 0 to 3. All access points have slot 0 and 1.

Verify XOR radio role sniffer configuration

Verify XOR radio role sniffer configuration.

To verify the XOR radio role sniffer configuration for a given AP, use this command:

```
Device# show ap name AP687D.B45C.189C config slot 0

Sniffing                                        : Enabled
Sniff Channel                                   : 6

Examples for sniffer configurations and monitoring

Sniffer configurations and monitoring examples.

This example shows how to configure an AP as sniffer:

```
Device# ap name access1 mode sniffer
```

This example shows how to enable sniffing on the AP:

```
Device# ap name sniffer dot11 5ghz sniff 44 1.1.1.1
```

This example shows how to disable sniffing on the AP:

```
Device# ap name access1 no sniff dot11b
```

This example shows how to display the sniffing configuration details:

```
Device# show ap name access1 config dot11 24ghz
Device# show ap name access1 config slot 0
```

37 Monitor Mode

Topics:

- Monitor mode

Monitor mode

Introduces the fundamental concepts of Monitor Mode in wireless deployments and provides guidance for enabling Monitor Mode using both GUI and CLI interfaces.

A monitor mode is a wireless operational mode that

- optimizes the monitoring of 802.11b/g/x network channels
- enhances location calculation for Radio Frequency Identification (RFID) tags, and
- allows limited channel scanning.

Key features of monitor mode

- Channel optimization: Optimize the monitoring by limiting the scanning to 2.4-GHz channels, such as 1, 6, and 11.
- RFID tag tracking: Enable precise tag-tracking by using specific operational frequencies.

AP mode transition

You can move an AP to a particular mode (sensor mode to local mode or FlexConnect mode) using the site tag with the corresponding mode. If the AP is not tagged to any mode, it uses the default site tag mode.

> **Tip**
>
> To optimize operational efficiency, ensure that the AP is tagged correctly.

returning AP to client-serving mode

You must use clear in AP mode to return the AP back to client-serving mode, for example the local mode or FlexConnect mode depending on the remote site tag configuration.

Enable monitor mode (GUI)

Enable monitor mode using GUI.

Switch the AP to monitor mode using the GUI.

Use these steps to enable monitor mode for the AP:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Access Points** page, expand the **All Access Points** section and click the name of the AP to edit.
3. In the **Edit AP** page, click the **General** tab and from the **AP Mode** drop-down list, choose **Monitor**.
4. Click **Update & Apply to Device**.
5. Choose the mode for the AP as **clear** to return the AP back to the client-serving mode depending on the remote site tag configuration.

The AP is now in monitor mode and can observe wireless traffic without serving clients.

Enable monitor mode (CLI)

Enable monitor mode using commands.

Enable and configure monitor mode on APs, ensuring they scan specific channels for network monitoring.

Follow these steps to enable monitor mode:

Procedure

1. Enable monitor mode for the AP.

   Example

   ```
   Device# ap name 3602a mode monitor
   ```

2. Configure the AP to scan only the Dynamic Channel Assignment (DCA) channels supported by its country of operation.

   Example

   ```
   Device# ap name 3602a monitor tracking-opt
   ```

3. Choose up to four specific 802.11b channels to be scanned by the AP.

   Example

   ```
   Device# ap name 3602a monitor dot11b 1 2 3 4
   ```

   In the United States, you can assign any value from 1 to 11 (inclusive) to the channel variable. Other countries support additional channels. You must assign at least one channel.

   Note

4. Configure the 802.11 6-Ghz radio role manual monitor.

   Example

   ```
   Device# ap name cisco-ap dot11 6ghz slot 3 radio role manual monitor
   ```

   slot 3 radio role manual monitor

5. View configuration and statistics of 802.11a or 802.11b or 6-GHz channel assignment.

   Example

   ```
   Device# show ap dot11 5ghz channel
   ```

6. View configuration and statistics summary of 6 GHz band APs.

Example

```
Device# show ap dot11 6ghz summary
```

The APs are set to monitor mode, scanning the specified channels and enabling effective network monitoring and channel assessment.

38 Management Mode Migration in Cisco Catalyst 916X Access Points

Topics:

- Management mode migration for Cisco Catalyst Wireless 916X Series AP

Management mode migration for Cisco Catalyst Wireless 916X Series AP

Outlines management modes for Cisco Catalyst Wireless 916X APs, describes dual-band radio support, and details procedures and considerations for migrating access points from DNA Management mode to Meraki Management mode using CLI or controller GUI.

A management mode is a configuration setting in networking devices that:

- determines how a device connects to the network
- controls the operating mode of access points, and
- allows flexibility through configurable options such as cloud-based or on-premises management.

Cisco Catalyst Wireless 916X APs support both 6 GHz and 5 GHz bands through dual-band slot 3 radios.

Feature History for management mode migration in Cisco catalyst wireless 916X access points
Table 52: Feature history

Release	Feature	Feature information
Cisco IOS XE Cupertino 17.9.1	Management Mode Migration in Cisco Catalyst Wireless 916X Series Access Points	This feature allows you to convert the AP mode between DNA Management mode and Meraki Management mode, depending on your requirements. **Note** The document explains the conversion from DNA Management mode to Meraki Management mode and not vice versa.

Management modes

- DNA Management mode: Allows the access point to utilize Cisco's Digital Network Architecture for advanced network capabilities and management.
- Meraki Management mode: Enables integration and management through Cisco's Meraki Cloud.

> **Note**
>
> The management mode migration configuration is specifically oriented for transitioning from DNA Management mode to Meraki Management mode and not the reverse. Migration can be configured through CLI in privileged EXEC mode at the AP level and from the controller GUI.

Regulatory domain

Regulatory domain details.

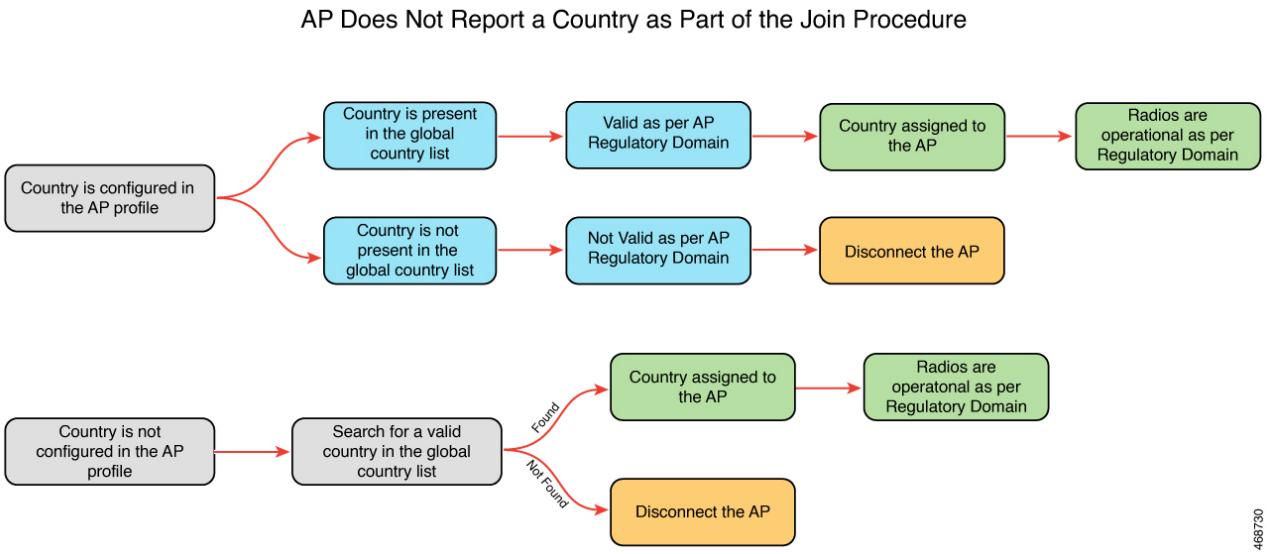
For regulatory domain support, Cisco Catalyst 916x Series APs (CW916x) support Rest of the World (RoW) and various fixed domains.

The Cisco Catalyst 916x Series APs support these domains:

- -B
- -E
- -A
- -Z
- -Q
- -I
- -R

These domains define the specific regions or countries where the Cisco Catalyst 916x can operate in compliance with local regulations.

AP join flow functionality



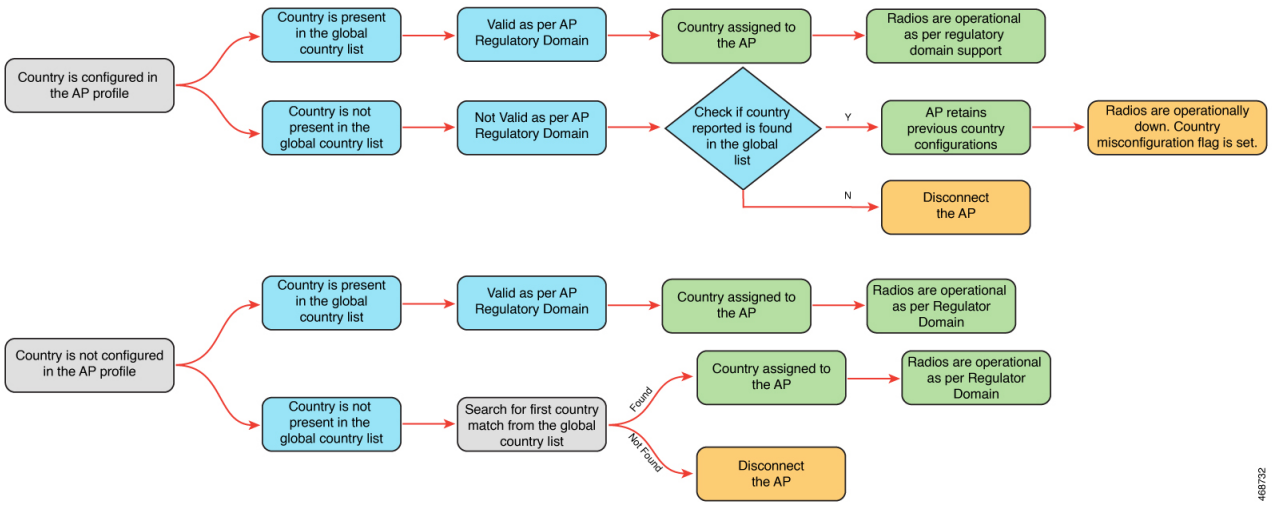
During the AP join flow, the AP passes the regulatory domain details and configured country to the controller. The controller assigns or validates the right country of operation. After validation based on the decision tree, the controller informs the AP of the country with which it should be configured.

Recommendation to configure AP regulatory domain

Use cases for regulatory domain.

AP configured with non-RoW regulatory domain

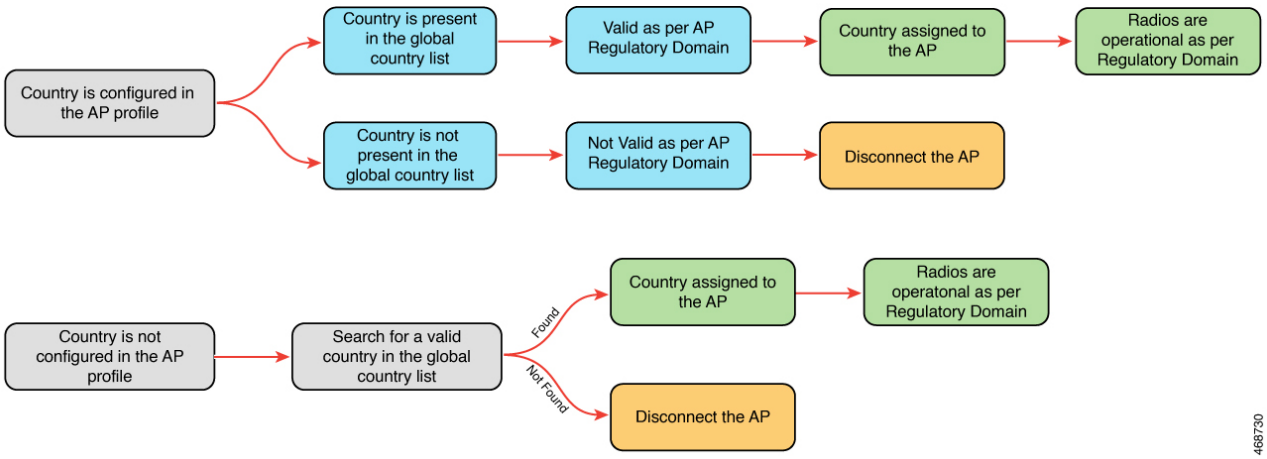
Case 1: AP does not report a country as part of the join procedure.



In the non-RoW regulatory domain, when an AP does not report a country as part of the join procedure, the process occurs:

- AP profile has a country configured.
  - If the country configured in the AP profile is present in the global country list, and is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
  - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, the AP is disconnected.
- AP profile does not have a country configured. Find a valid country from the global country list (the first match), as per the AP regulatory domain.
  - If the country is found, the country is assigned to the AP and the radios become operational as per the country or regulatory domain support.
  - If the country is not found, the AP is disconnected.

Case 2: AP reports a country as part of the join procedure.

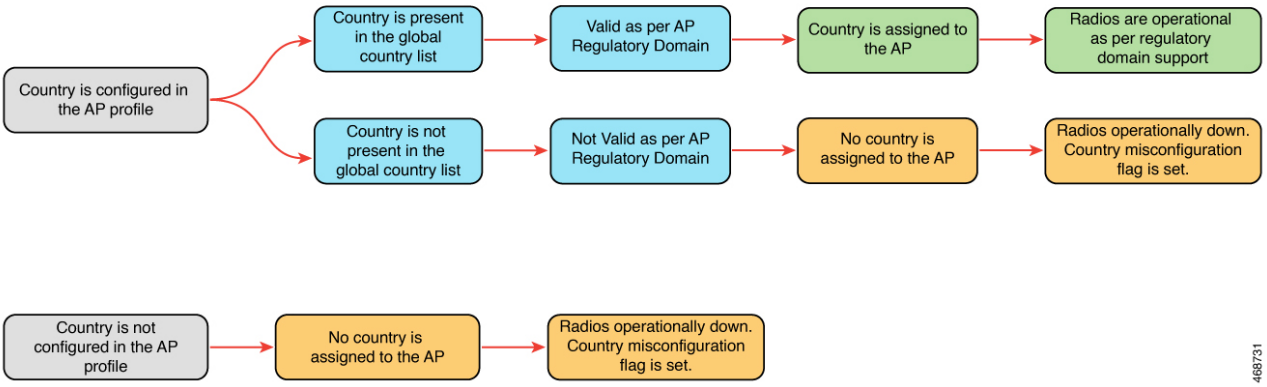


AP Reports Country as Part of the Join Procedure

In the non-RoW regulatory domain, when an AP reports a country as part of the join procedure, the following takes place:

- The AP profile has a country configured.
  - If the country configured in the AP profile is present in the global country list, and it is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
  - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, check the global country list to confirm the country's presence. If it is present in the global list, the AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set. If the country is not located in the global list, the AP is disconnected.
- The AP profile does not have a country configured.
  - If the country reported by the AP is found in the global country list, and is valid as per the AP regulatory domain, the country is assigned to the AP and the radios become operational as per the country or regulatory domain support.
  - If the country is not present in the list, search for the first country match from the global list. If the country is found, the country is assigned to the AP and the radios become operational. If the country is not found, the AP is disconnected.

AP Does Not Report a Country as Part of the Join Procedure



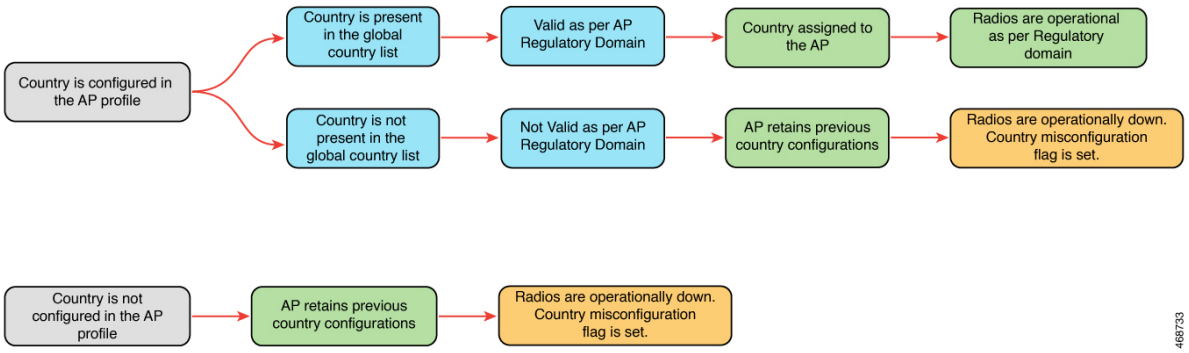
In the non-RoW regulatory domain, when an AP does not report a country as part of the join procedure, the following takes place:

- AP profile has a country configured.
  - If the country configured in the AP profile is present in the global country list, and is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
  - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, the AP is disconnected.
- AP profile does not have a country configured. Find a valid country from the global country list (the first match), as per the AP regulatory domain.
  - If the country is found, the country is assigned to the AP and the radios become operational as per the country or regulatory domain support.
  - If the country is not found, the AP is disconnected.

AP configured with RoW regulatory domain

Case 1: The AP does not report a country as part of the join procedure.

AP Does Not Report a Country as Part of the Join Procedure



In the RoW regulatory domain, when an AP does not report a country as part of the join procedure, this process occurs:

- The AP profile has a country configured.
  - If the country configured in the AP profile is present in the global country list, and is valid as per the AP regulatory domain, the country configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
  - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, country is not assigned to the AP and radios are not operational, and the country misconfiguration flag is set.
- If the AP profile does not have a country configured, the country is not assigned to the AP and radios are not operational, and the country misconfiguration flag is set.

Case 2: The AP reports a country as part of the join procedure.

AP Reports a Country as Part of the Join Procedure

In the RoW regulatory domain, when an AP reports a country as part of the join procedure, this happens:

- The AP profile has a country configured.
  - If the country configured in the AP profile is present in the global country list, and it is valid as per the AP regulatory domain, the country that is configured in the AP profile is assigned to the AP. Radios become operational as per the country or regulatory domain support.
  - If the country configured in the AP profile is not present in the global country list, and is not valid as per the AP regulatory domain, the AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set.
- The AP retains the previous country configuration and the radios are not operational with the country misconfiguration flag set.

Configure management mode migration (GUI)

Configure Management Mode Migration using GUI.

Use the GUI to transition APs from DNA management mode to Meraki management mode. This improves network management efficiency.

Before you begin

You must configure the country code on the AP profile. To configure the country code, navigate to **Configuration** > **Tags & Profiles** > **AP Join** page. Click an AP profile to edit. In the **General** tab, select the country code from the drop-down list.

Use these steps to migrate the management mode using the GUI:

Procedure

1. Choose **Configuration** > **Wireless** > **Migrate to Meraki Management Mode**.
2. Select the APs you need by checking the boxes next to them from the displayed list.
   The **Migrate to Meraki Management Mode** button is enabled.
3. Click **Migrate to Meraki Management Mode** button to perform a validation check on the selected APs. If the validation check is successful, the **Next** button is enabled.
4. Click **Next** to start the process.
5. On the **Confirm Management Mode Migration** window, perform these actions:
   a. Select the **Agree and continue** check box.
   b. Click **Yes** to confirm.

   The **Management Mode Migration Successful** section displays the APs that were migrated to the Meraki management mode. The **Management Mode Migration Failed** section displays the APs that were retained in DNA management mode.
6. Click **Restart Workflow** to restart the workflow for APs that did not migrate from DNA management mode to Meraki management mode.

APs migrate to Meraki management mode. APs that fail to migrate remain in DNA management mode, allowing for further troubleshooting or additional attempts.

Export APs migrated to Meraki management mode (GUI)

Export the list of Meraki management mode-migrated APs to ensure information is available for further use, or integration into other tools.

You can export the details about the Meraki management mode-migrated APs either from the **Change to Meraki Persona** tab after the workflow is completed or from the **Previously changed APs** tab.

Use these steps to export Meraki management mode-migrated APs:

Procedure

1. Choose **Configuration** > **Wireless** > **Migrate to Meraki Management Mode**.
2. Click **Export** to export the list of APs.
3. Select whether you want to export only the current page or all pages. Click **Yes** to continue.
4. On the **Export** window, select the export method. The available options are:
   - **Serial Number**
   - **JSON**
   - **Export to Meraki Dashboard**

> **Note**
>
> We recommend the Export to Meraki Dashboard option as you can directly export the migrated APs information into the Meraki Dashboard.

5. Click **Copy** to copy the migrated APs. Click **Download** and save the file location.

The list of migrated APs was successfuly exported, ensuring that the data is readily available for review, storage, or integration.

Configure the access point management mode (CLI)

Configure the AP Management Mode using commands.

Change the management mode of an AP to Meraki using CLI.

Before you begin

Ensure that the AP is compatible with Meraki to run any of the EXEC commands. To verify, use the **show ap management-mode meraki capability summary** command.

> **Note**
>
> If the country code is misconfigured, the change of management mode will not be allowed for any of the EXEC commands, except the **force** command.
>
> If the regulatory domain is misconfigured for any slot, the change of management mode is not allowed for any of the EXEC commands, except the **force** command.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter the password, if prompted.

2. Change the AP management mode to Meraki.

   Example

   ```
   Device# ap name <i>Cisco-AP-name</i> management-mode meraki
   Device# ap name Cisco-AP-name management-mode meraki force
   Device# ap name Cisco-AP-name management-mode meraki noprompt
   Device# ap name Cisco-AP-name management-mode meraki force noprompt
   ```

   Here, **force** skips the validations at the controller and attempts Meraki management mode change at the AP.

noprompt skips the user prompt for attempting AP management mode change.

3. Optional: Clear the Meraki AP-related data.

Example

```
Device# clear ap meraki stats
```

The AP is configured to the Meraki management mode.

Verify the management mode migration details

Verify the management mode migration details

To view the summary of the Meraki-capable AP information, run this command:

```
Device# show ap management-mode meraki capability summary
AP Name                    AP Model             Radio MAC        MAC Address
     AP Serial Number       Meraki Serial Number
-------------------------------------------------------------------------------
APXXXD.BXXX.1XXX           CW9162I             6XXd.bXXe.eXX0   6XXd.bXXe.eXX0
    FOCXXXXXB90             FOCXXXXXB90
```

To view the failure summary of the AP along with the migration attempt timestamp, run this command:

```
Device# show ap management-mode meraki failure summary
AP Name               AP Model          Radio MAC        MAC Address
Conversion Attempt        AP Serial Number       Meraki Serial Number   Reason
 Code
-------------------------------------------------------------------------------
APXXXD.BXXC.1         CW9162I           6XXd.bXXe.eXX0   6XXd.bXXe.eXX0
03/03/2022 17:17:42 IST   FOCXXXXXB90            FOCXXXXXB90
Regulatory domain not set
```

To view the successful Meraki management mode migration attempts of all the APs, run this command:

```
Device# show ap management-mode meraki change summary
AP Name                   AP Model          Radio MAC        MAC Address
Conversion Timestamp       AP Serial Number        Meraki Serial Number
-------------------------------------------------------------------------------
APXXXX.3XXX.EXXX          CW9166I-B         1XXX.2XXX.1100   ccXX.3XXX.eXX0
05/02/2022 07:48:56 CST    KWC2XXXXX5G             Q5XX-4XXX-K7XX
```

39 Configure the controller for FlexConnect

Topics:

- FlexConnect Authentication
- Configure FlexConnect
- NAT-PAT functionalities in FlexConnect
- Split tunneling for FlexConnect
- VLAN-based central switching for FlexConnect
- OfficeExtend AP for FlexConnect
- Proxy address resolution protocol
- Overlapping client IP address in flex deployment
- FlexConnect high scale mode
- Flex resilient with Flex and bridge modes
- SuiteB ciphers in FlexConnect mode

Configure the controller for FlexConnect.

You can configure the controller for FlexConnect in either centrally switched WLAN or locally switched WLAN environments.

Table 53: WLAN scenarios

The controller configuration for FlexConnect consists of creating centrally switched and locally switched WLANs. This table shows three WLAN scenarios.

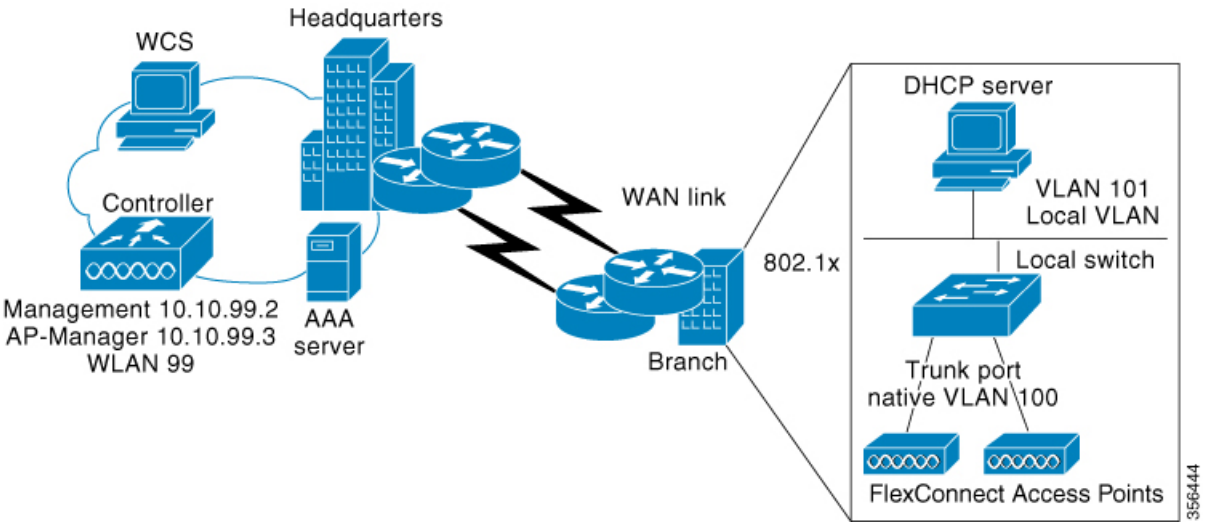
WLAN	Security	Authentication	Switching	Interface mapping (GUEST VLAN)
Employee	WPA1+WPA2	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local	WPA1+WPA2 (PSK)	Local	Local	101 (locally switched GUEST VLAN)
Guest-central	Web authentication	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local-auth	WPA1+WPA2	Local	Local	101 (locally switched VLAN)

FlexConnect Authentication

Introduces FlexConnect architecture, authentication workflows, controller discovery, switching modes, local authentication, RADIUS server configuration, operational restrictions, and provides procedures for configuring policy tags, site tags, ACLs, and applying access policies through both GUI and CLI.

A FlexConnect authentication mode is a WLAN operating state that

- defines how a FlexConnect AP handles client authentication and data switching
- changes its behavior based on connection status to the controller, and
- enables resilient client connectivity during both connected and standalone operation.



Locally switched: The AP forwards client data directly to the local LAN or VLAN at the site instead of tunneling it through the controller.

Centrally switched: The AP forwards the client's data traffic to the controller, depending on the WLAN configuration.

FlexConnect is a wireless solution for branch office and remote office deployments. It enables customers to configure and control access points (AP) in a branch or remote office from the corporate office through a wide area network (WAN) link without deploying a controller in each office. The FlexConnect access points can also switch client data traffic locally and perform client authentication locally when their connection to the controller is lost. When they are connected to the controller, they can also send traffic back to the controller. FlexConnect access points support multiple SSIDs. In the connected mode, the FlexConnect access point can also perform local authentication.

An access point does not have to reboot when moving from local mode to FlexConnect mode and vice-versa.

FlexConnect Deployment

The embedded wireless controller software uses a more robust fault-tolerance methodology with FlexConnect APs. Whenever a FlexConnect AP disassociates from controller, it moves to the standalone mode. Centrally switched clients are disassociated. However, the FlexConnect access point continues to serve locally switched clients. When a FlexConnect AP loses and rejoins its primary or identically configured secondary controller, locally switched client sessions are maintained, providing seamless connectivity.

After the client connection is established, the controller does not restore the original attributes of the client. The client username, current rate and supported rates, and listen interval values are reset to the default or new configured values only after the session timer expires.

The controller can send multicast packets in the form of unicast or multicast packets to an access point. In FlexConnect mode, an access point can receive only multicast packets.

In Cisco Catalyst 9800 Series Wireless Controller, you can define a flex connect site. A FlexConnect site can have a flex connect profile associate with it. You can have a maximum of 100 access points for each flex connect site.

FlexConnect access points support a one-to-one network address translation (NAT) configuration. They also support PAT for all features except true multicast. Multicast is supported across NAT boundaries when configured using the Unicast option. FlexConnect access points also support a many-to-one NAT or PAT boundary, except when you want true multicast to operate for all centrally switched WLANs.

Workgroup Bridge and Universal Workgroup Bridge modes are supported on FlexConnect APs for locally switched clients.

FlexConnect supports IPv6 clients by bridging traffic to the local VLAN, similar to IPv4 operation.

- An office with intermittent WAN connectivity keeps wireless clients connected using local authentication, with data switched locally until the central controller is available again.
- A FlexConnect AP at a remote branch uses backup RADIUS for 802.1X authentication during WAN outages.

Analogy: retail chain

Imagine a retail chain with a central headquarters (controller) and a branch store (the FlexConnect AP).

Normal day: Every time a customer wants to make a purchase, the cashier phones headquarters for approval and processing. This is like **central authentication and switching**.

Local authentication (policy choice): Even on a normal day, the branch can be configured to keep a small credit-card terminal in the store. If management decides to use it, the cashier can approve transactions locally without phoning headquarters. The headquarters link is still up, but the store chooses to handle the verification itself. That terminal is **“local authentication"** .

Stand-alone mode (connectivity condition): One day the phone lines to headquarters go down. The branch is forced to rely on its credit-card terminal, whether it originally planned to or not, if it wants to keep making sales. The store switches on its emergency lights, keeps serving customers, and records the day’s sales to upload later. That forced independence is **“standalone mode”**.

Key Takeaway

Standalone mode is the situation (phone lines down).

Local authentication is the tool (the in-store terminal) that lets the store keep serving customers—even when the phone lines are fine and especially when they are not.

How FlexConnect authentication works

Summary

FlexConnect authentication enables wireless APs to maintain client connectivity and authentication in various network scenarios, either by connecting to a central controller or operating autonomously. This process is essential for branch offices or remote sites with unreliable WAN links.

The key components involved in the process are:

- FlexConnect AP: Discovers controllers, downloads configuration, and performs client authentication and data switching either locally or through the controller.
- The controller: Centralizes configuration management and client authentication when available.
- Client devices: Attempt to authenticate and connect to the network through FlexConnect APs.
- RADIUS server: Provides authentication services, either centrally through the controller or locally through a backup server in standalone modes.

Workflow

The process involves the following stages:

1. **Controller Discovery and Join**
   - When a FlexConnect AP boots up, it searches for and joins a wireless LAN controller, downloading the latest configuration and software image.

When...	Then...	And...
The controller is reachable, the AP enters connected mode.	The controller performs central authentication.	Based on WLAN configuration • client data is switched either through the controller (central switching), or • locally at the AP (local switching).
The controller is not reachable, the AP enters standalone mode.	The AP performs local authentication using stored configuration and, if needed, a backup RADIUS server.	• Client data is switched locally. • Special states (such as “authentication down, local switching”) manage client behavior when authentication cannot occur. When operating locally, guest authentication and local RADIUS on the controller are not supported.

2. **Failover and Recovery**
   - If controller connectivity is lost, the AP attempts to reach the gateway via ARP and retries controller discovery.
   - If discovery fails, it attempts DHCP renewal and, if still unsuccessful after multiple attempts, falls back to static IP and reboots to recover.
3. **Return to Connected Mode**

   Upon reconnecting to the controller, the AP disassociates clients, applies new configuration, and resumes normal connectivity, with central authentication and state management.

Result

FlexConnect authentication ensures clients can maintain connectivity and authentication even during network disruptions, supports flexible deployment models, and reduces branch office WAN dependency.

Controller discovery methods

When a FlexConnect AP boots up, it searches for a controller. If it finds one, it joins the controller, downloads the latest software and configuration, and initializes the radio. The configuration is saved in nonvolatile memory to support standalone mode if the controller becomes unreachable.

A FlexConnect AP can discover the controller’s IP address through multiple methods:

- **DHCP-based discovery:** If the access point gets its IP from a DHCP server, it uses CAPWAP or LWAPP discovery. OTAP is not supported.
- **Static IP discovery**: If configured with a static IP, the access point can use all discovery methods except DHCP option 43. DNS resolution is recommended if Layer 3 broadcast fails. With DNS, any AP with a static IP address that knows of a DNS server can find at least one controller.
- **Priming**: For remote networks without CAPWAP or LWAPP, priming allows manual configuration through the CLI to specify the controller.

FlexConnect authentication and switching modes

> **Note**
>
> The LEDs on the AP change as the device enters different FlexConnect modes. See the hardware installation guide for your AP for information on LED patterns.

When a client associates with a FlexConnect AP, the AP sends all authentication messages to the controller and, based on the WLAN configuration, either switches the client's data packets locally (locally switched) or sends them to the controller (centrally switched).

For client authentication (open, shared, EAP, web authentication, and NAC) and data packets, the WLAN operates in one of the following states, determined by its configuration and the controller connectivity status:

- Central authentication, central switching: The controller handles both client authentication and data switching. All client data is tunneled to the controller. This state is valid only in the connected mode.
- Central authentication, local switching–In this state, the controller handles client authentication, and the FlexConnect AP switches data packets locally. After the client authenticates successfully, the controller sends a configuration command with a new payload to instruct the FlexConnect AP to start switching data packets locally. This message is sent per client. This state is applicable only in connected mode.
- Local authentication, local switching: The AP both authenticates clients and switches data locally. This state works in both connected and standalone mode.
- Authentication down, switch down: The WLAN disassociates clients and stops sending beacons and probes. Valid for both connected and standalone modes.
- Authentication down, local switching: New client authentication is rejected, but existing client sessions are kept alive. Valid in standalone mode.

In the connected mode, the controller receives only minimal information about locally authenticated clients. Some information not available to the controller are:

- Policy type
- Access VLAN
- VLAN name
- Supported rates
- Encryption cipher

When a FlexConnect AP is unable to reach the controller, WLANs configured with open, shared, WPA-PSK, or WPA2-PSK authentication continue to authenticate clients locally if an external RADIUS server is available. If the controller becomes reachable again, all clients are disassociated and a new configuration is applied before connectivity resumes.

In web-authentication mode, client DNS replies must pass through the controller during authentication. After successful web authentication, all traffic switches locally.

Standalone Mode

When a FlexConnect AP cannot reach the controller, it automatically enters standalone mode and begins authenticating clients on its own

Behavior in standalone mode

- WLANs configured for open, shared, WPA-PSK, or WPA2-PSK authentication enter the **local authentication, local switching** state and continue new client authentications.

- WLANs configured for 802.1X, WPA-802.1X, WPA2-802.1X, or Cisco Centralized Key Management require an external or local RADIUS server to remain operational.
- WLANs configured for central switching move to **authentication down, switching down**; WLANs configured for local switching move to **authentication down, local switching**
- The AP forwards data frames locally while it authenticates clients.

When a FlexConnect AP enters a standalone mode, the AP checks whether it is able to reach the default gateway through ARP. If so, it will continue to try and reach the controller .

If the AP fails to establish the ARP:

- The AP attempts to discover for five times and if it still cannot find the controller , it tries to renew the DHCP on the ethernet interface to get a new DHCP IP.
- The AP will retry for five times, and if that fails, the AP will renew the IP address of the interface again, this will happen for three attempts.
- If the three attempts fail, the AP will fall back to the static IP and will reboot (only if the AP is configured with a static IP).
- Reboot is done to remove the possibility of any unknown error the AP configuration.

Local authentication in a FlexConnect AP

Local authentication in a FlexConnect AP is an authentication method in which

- the FlexConnect AP independently authenticates clients without forwarding authentication requests to a central controller
- client data packets are switched locally by the AP, reducing round-trip latency and dependence on WAN bandwidth
- authentication capabilities are built into the AP for handling protocols like 802.1X, WPA-PSK, WPA2-PSK, and others reduces the latency requirements of the branch office, and
- is useful where you cannot maintain a remote office setup of a minimum bandwidth of 128 kbps with the round-trip latency no greater than 100 ms and the maximum transmission unit (MTU) no smaller than 576 bytes.

Additional information

- Do not enable guest authentication on WLANs with FlexConnect local authentication; guest authentication is unsupported in this configuration.
- Do not use local RADIUS authentication on the controller for FlexConnect local authentication-enabled WLANs; it is not supported.
- Once the client has been authenticated, roaming is only supported after the controller and the other FlexConnect access points in the group are updated with the client information.

Local and backup RADIUS server configuration

-
- When connected to a central controller, FlexConnect APs use the controller's primary RADIUS servers in the specified order unless overridden for a particular WLAN. The order is specified on the **RADIUS Authentication Servers** window or using the the **config radius auth add** command
- In standalone mode, each FlexConnect AP must have its own backup RADIUS server to perform 802.1X EAP authentication for clients. The controller itself does not use a backup RADIUS server in this mode.

- You can configure a backup RADIUS server for individual FlexConnect APs in standalone mode by using the controller CLI or for groups of FlexConnect APs in standalone mode by using either the GUI or CLI. An AP-specific backup RADIUS configuration overrides any group configuration.

> **Note**
>
> A controller does not use a backup RADIUS server. The controller uses the backup RADIUS server in local authentication mode.

WLAN authentication and switching states

When a primary RADIUS server becomes unavailable, WLANs will enter either:

- **Authentication down, switching down**

  state if the WLAN was configured for central switching
- **Authentication down, local switching** state if the WLAN was configured for local switching

Web authentication and DNS handling

When web-authentication is used on FlexConnect APs at a remote site, the clients get the IP address from the remote local subnet.

To resolve the initial URL request, the DNS is accessible through the subnet's default gateway. In order for the controller to intercept and redirect the DNS query return packets, these packets must reach the controller at the data center through a CAPWAP connection. During the web-authentication process, the FlexConnect APs allows only DNS and DHCP messages; the APs forward the DNS reply messages to the controller before web-authentication for the client is complete. After web-authentication for the client is complete, all the traffic is switched locally.

Restrictions

- OTAP is not supported.
- After the AP reboots with the new controller software, convert it to FlexConnect mode.
- 802.1X authentication on the AUX port is unsupported for Cisco Aironet 2700 series FlexConnect APs.
- FlexConnect passive client mode disables IP Learn timeout by default in local switching, central authentication deployments.
- When a FlexConnect AP enters standalone mode, only WLANs configured for open, shared, WPA-PSK, or WPA2-PSK authentication support local authentication for new clients; 802.1X types require an external or local RADIUS server.
- When FlexConnect APs are connected to the controller (rather than in standalone mode), the controller uses its primary RADIUS servers and accesses them in the order specified on the RADIUS Authentication Servers page or in the **config radius auth add** CLI command (unless the server order is overridden for a particular WLAN). However, to support 802.1X EAP authentication, FlexConnect APs in standalone mode need to have their own backup RADIUS server to authenticate clients.

> **Note**
>
> A controller does not use a backup RADIUS server. The controller uses the backup RADIUS server in local authentication mode.

When the FlexConnect AP cannot reach its default gateway through ARP and cannot discover the controller, it attempts multiple DHCP renewals and reboots if configured with a static IP to recover connectivity; controller discovery failures trigger fallback behavior.

If the AP fails to establish the ARP, this happens:

- The AP attempts to discover for five times and if it still cannot find the controller, it tries to renew the DHCP on the ethernet interface to get a new DHCP IP.
- The AP will retry for five times, and if that fails, the AP will renew the IP address of the interface again, this will happen for three attempts.
- If the three attempts fail, the AP will fall back to the static IP and will reboot (only if the AP is configured with a static IP).
- The AP reboots to eliminate potential configuration errors.

Guidelines and restrictions for FlexConnect

FlexConnect guidelines and restrictions.

Configuration Changes

- When you apply a configuration change to a locally switched WLAN, the access point resets the radio, causing associated client devices to disassociate, including those not associated with the modified WLAN. Modify the configuration only during a maintenance window. This is applicable when a centrally switched WLAN is changed to a locally switched WLAN.
- This guideline is specific to Wave 1 APs, and not for Wave 2 APs or 11AX APs.

VLAN and Switched WLANs

- FlexConnect mode can support only 16 VLANs per AP.
- NAC out-of-band integration is supported only on WLANs configured for FlexConnect central switching, not for local switching.
- FlexConnect access points with locally switched WLANs cannot perform IP source guard and prevent ARP spoofing.

Network and Client Requirements

- You can deploy a FlexConnect access point with either a static IP address or a DHCP address. Ensure a DHCP server is available locally and able to provide the IP address for the access point at bootup.
- FlexConnect supports up to 4 fragmented packets or a 576-byte MTU WAN link.
- Round-trip latency must not exceed 300 milliseconds (ms) between the access point and the controller, and CAPWAP control packets must be prioritized over all other traffic.

Roaming and Associations

When a client roams from one AP to another and the roaming is successful, this happens:

- The client does not send any traffic to the new AP.

- The client's state is IP LEARN pending.
- The client is deauthenticated after 180 seconds, if there is no traffic for the entire duration. In case the DHCP Required flag is set, the deauthentication occurs after 60 seconds.

Authentication and Support

- FlexConnect APs do not forward the DHCP packets after Change of Authorization (CoA) and change of VLANs using 802.1X encryption. You must disconnect the client from the WLAN and reconnect the client to enable the client to get an IP address in the second VLAN.
- The configuration on the controller must be the same between the time the access point went into standalone mode and the time the access point came back to connected mode.
- Local authentication fallback is not supported when a user is not available in the external RADIUS server.

Configuration Practices

- In the FlexConnect mode, use a named site tag instead of default-site-tag. If you use default-site-tag, the client Pairwise Master Key (PMK) is not sent to APs. This results in client roam and reassociation issues.

Rate limiting per SSID is not supported in FlexConnect local switching mode

- Rate limiting per SSID is not supported in FlexConnect local switching mode.
- Rate limiting is enforced per flow (5-tuple) and not per SSID or per client.
- For rate limiting to work as expected, FlexConnect central switching mode should be used.
- In FlexConnect local switching mode, QoS policies are applied at the AP level.

Configure a site tag (CLI)

Configure a site tag using commands.

Configure a site tag using CLI to centrally manage configurations for APs within a network. By completing this task, you streamline the management of configuration profiles and associated devices on the network.

Use these steps to configure a site tag using CLI:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure site tag and enter site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site default-site-tag
   ```

3. Move the AP to FlexConnect mode.

Example

```
Device(config-site-tag)# no local-site
```

> **Note**
>
> **no local-site** must be configured before configuring flex-profile. Otherwise, flex-profile will not be applied to the site tag.

4. Map a flex profile to a site tag.

   Example

   ```
   Device(config-site-tag)# flex-profile rr-xyz-flex-profile
   ```

5. Assign an AP profile to the wireless site.

   Example

   ```
   Device(config-site-tag)# ap-profile xyz-ap-profile
   ```

6. Add a description for the site tag.

   Example

   ```
   Device(config-site-tag)# description "default site tag"
   ```

7. Save the configuration, exit the configuration mode, and return to privileged EXEC mode.

   Example

   ```
   Device(config-site-tag)# end
   ```

8. Display the summary of site tags.

   Example

   ```
   Device# show wireless tag site summary
   ```

You configured the new site tag for the network. Now visible in the system, the site tag allows you to efficiently manage AP profiles and flex profiles associated with specific network sites.

Configure a policy tag (CLI)

Configure a policy tag using commands.

Create and apply a policy tag to group wireless local area network (WLAN) and policy profiles for your network configuration.

Use this task when you need to define or update policy tags for your wireless network devices using the CLI.

Before you begin

- Prepare unique names for policy tags using ASCII characters (32 to 126, no leading or trailing spaces).
- Identify the WLAN and policy profiles you plan to map.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config-policy-tag)# wireless tag policy default-policy-tag
   ```

   Note

   When performing local web authentication, the clients connected to a controller get disconnected intermittently before session timeout.

3. Add a description to a policy tag.

   Example

   ```
   Device(config-policy-tag)# description "default-policy-tag"
   ```

4. Map a remote-LAN profile to a policy profile.

   Example

   ```
   Device(config-policy-tag)# remote-lan remote-lan-name policy
   profile-policy-name port-id port-id-number
   ```

5. Map a policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan wlan-name policy profile-policy-name
   ```

> **Note**
>
> Ensure that the WLAN profile is not used by any other profiles. If the AP uses the default profile, ensure that the **no central switching** command is configured on other profiles.

6. Exit policy tag configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

7. Optional: Display the configured policy tags.

Example

```
Device# show wireless tag policy summary
```

> **Note**
>
> To view detailed information about a policy tag, use the **show wireless tag policy detailed** *policy-tag-name* command.

Your device has the new policy tag applied. The mapped WLAN and policy profiles are now active based on your configuration.

What to do next

Verify that connected devices use the updated policy tag and the expected network policies are applied.

Attach policy and site tags to an access point (GUI)

Attach a policy tag and a site tag to an AP using GUI.

This task allows you to efficiently organize and manage access points by assigning specific policy and site tags through GUI.

Use these steps to assign policy and site tags to an AP using GUI:

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the **Access Point** name.
3. Go to the **Tags** section.
4. Choose the **Policy Tag** from the **Policy** drop-down list.
5. Choose the **Site Tag** from the **Site** drop-down list.

6. Click **Update and Apply to Device**.

The AP has the designated policy and site tags, ensuring it operates under defined network conditions and policy settings.

Attach policy tag and site tag to an AP (CLI)

Attach Policy Tag and Site Tag to an AP using commands.

Assign a policy tag and site tag to an AP using the CLI.

Use this procedure to associate specific network policies and locations with an AP in your Cisco wireless deployment.

Before you begin

Make sure you have the wired MAC address of the AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco AP and enters AP profile configuration mode.

   Example

   ```
   Device(config)# ap F866.F267.7DFB
   ```

   Note

   The *mac-address* should be a wired mac address.

3. Map a policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag rr-xyz-policy-tag
   ```

4. Map a site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag rr-xyz-site
   ```

5. Associate the RF tag.

Example

```
Device(config-ap-tag)# rf-tag rf-tag1
```

6. Save the configuration, exit configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-ap-tag)# end
```

7. Optional: Display AP details and the tags associated to it.

Example

```
Device# show ap tag summary
```

8. Display the AP name with tag information.

Example

```
Device# show ap name "ap-name" tag info
```

9. Optional: Display the AP name with tag details.

Example

```
Device# show ap name ap-name tag detail
```

The AP is now associated with the specified policy, site, and optionally, RF tags you selected

Link an ACL policy to the defined ACL (GUI)

Link an ACL policy to the defined ACL using GUI.

The task of linking an ACL policy to a defined ACL using the GUI enables you to assign security rules to specific network traffic based on ACL configurations.

Use these steps to link an ACL policy to a defined ACL using the GUI

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. Click **Add**.
3. In the **General** tab, enter the **Name** of the Flex Profile. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
4. In the **Policy ACL** tab, click **Add**.
5. Select the ACL from the **ACL Name** drop-down list and click **Save**.
6. Click **Apply to Device**.

The ACL policy is linked to the defined ACL and applied to the specified device.

Apply access control lists on FlexConnect

Apply ACLs on FlexConnect using commands.

Apply Access Control Lists (ACLs) on a FlexConnect wireless profile to filter packet movement through a network. Use these steps to apply ACLs on FlexConnect.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless flex profile and enter wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex Flex-profile-1
   ```

3. Configure an ACL policy.

   Example

   ```
   Device(config-wireless-flex-profile)# acl-policy ACL1
   ```

   Access control lists (ACLs) perform packet filtering to control the movement of packets through a network.

4. Return to wireless flex profile configuration mode.

   Example

   ```
   Device(config-wireless-flex-profile-acl)# exit
   ```

5. Configure native vlan-id information.

   Example

   ```
   Device(config-wireless-flex-profile)# native-vlan-id 25
   ```

6. Configure a VLAN.

   Example

   ```
   Device(config-wireless-flex-profile)# vlan-name VLAN0169
   ```

7. Configure an ACL for the interface.

   Example

   ```
   Device(config-wireless-flex-profile-vlan)# acl ACL1
   ```

8. Configure VLAN information.

Example

```
Device(config-wireless-flex-profile-vlan)# vlan-id 169
```

The ACLs are applied to the FlexConnect wireless profile, ensuring controlled packet filtering through configured VLAN settings.

Configure FlexConnect

Details FlexConnect configuration processes, including remote site switch setup, controller configuration, local and central switching (via GUI and CLI), AP configuration for FlexConnect and local authentication, client WLAN connectivity, Ethernet fallback, and authentication scenarios with deployment examples.

Configure the switch at a remote site

Configure a switch at a remote site.

Configure a switch to support a FlexConnect access point at a remote site by ensuring proper VLAN and IP address settings.

Use the steps to configure the switch at a remote site

Procedure

1. Attach the AP by connecting the FlexConnect access point to either a trunk or an access port on the switch.

> **Note**
>
> The sample configuration in this procedure shows the FlexConnect access point connected to a trunk port on the switch.

2. This example configuration guides you on configuring a switch to support a FlexConnect AP.

   In this sample configuration, the FlexConnect access point is connected to the trunk interface FastEthernet 1/0/2 with native VLAN 100. The access point needs IP connectivity on the native VLAN. The remote site has local servers or resources on VLAN 101. A DHCP pool is created in the local switch for both the VLANs in the switch. The first DHCP pool (NATIVE) is used by the FlexConnect access point, and the second DHCP pool (LOCAL-SWITCH) is used by the clients when they associate to a WLAN that is locally switched.

```
.
.
.
ip dhcp pool NATIVE
   network 209.165.200.224 255.255.255.224
   default-router 209.165.200.225
   dns-server 192.168.100.167
!
ip dhcp pool LOCAL-SWITCH
```

```
   network 209.165.201.224 255.255.255.224
   default-router 209.165.201.225
   dns-server 192.168.100.167
!
interface Gig1/0/1
 description Uplink port
 no switchport
 ip address 209.165.202.225 255.255.255.224
!
interface Gig1/0/2
 description the Access Point port
 switchport trunk encapsulation dot1q
 switchport trunk native vlan 100
 switchport trunk allowed vlan 101
 switchport mode trunk
!
interface Vlan100
 ip address 209.165.200.225 255.255.255.224
!
interface Vlan101
 ip address 209.165.201.225 255.255.255.224
end
!
.
.
.
```

The switch is configured to support the FlexConnect access point, enabling network connectivity for the access point and local servers or resources in the VLANs specified.

Configure the controller for FlexConnect

Configure the controller for FlexConnect.

You can configure the controller for FlexConnect in either centrally switched WLAN or locally switched WLAN environments.

Table 54: WLAN scenarios

The controller configuration for FlexConnect consists of creating centrally switched and locally switched WLANs. This table shows three WLAN scenarios.

WLAN	Security	Authentication	Switching	Interface mapping (GUEST VLAN)
Employee	WPA1+WPA2	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local	WPA1+WPA2 (PSK)	Local	Local	101 (locally switched GUEST VLAN)
Guest-central	Web authentication	Central	Central	Management (centrally switched GUEST VLAN)
Employee-local-auth	WPA1+WPA2	Local	Local	101 (locally switched VLAN)

Configure local switching in FlexConnect mode (GUI)

Configure local switching in FlexConnect mode using GUI.

Enable local switching for a device operating in FlexConnect mode using the GUI.

Use these steps to configure local switching.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, click the name of a policy profile to edit it or click **Add** to create a new one.
3. In the **Add/Edit Policy Profile** window that is displayed, uncheck the **Central Switching** check box.
4. Click **Update & Apply to Device**.

The device is now configured to use local switching in FlexConnect mode.

Configure local switching in FlexConnect mode (CLI)

Configure local switching in FlexConnect mode using commands.

Configure a WLAN for local switching when operating in FlexConnect mode, enabling WLANs to be locally switched at the AP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile
   policy rr-xyz-policy-1
   ```

3. Configure the WLAN for local switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The WLAN operates with local switching at the AP, allowing the WLAN data traffic to be processed locally rather than routed through a central controller.

Configure central switching in FlexConnect mode (GUI)

Configure central switching in FlexConnect mode using GUI.

Enable or disable central switch mode in FlexConnect to manage traffic more effectively based on your network setup.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. On the **Policy Profile** page, select a policy.
3. In the **Edit Policy Profile** window, in General Tab, use the slider to enable or disable **Central Switching**.
4. Click **Update & Apply to Device**.

Central switch mode has been configured as specified, and the network policy is updated according to your current setup needs.

Configure central switching in FlexConnect mode (CLI)

Configure central switching in FlexConnect mode using commands.

Establish central switching in FlexConnect mode on your device using the CLI.

Use these steps to configure central switching in FlexConnect mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device
   config)# wireless profile policy rr-xyz-policy-1
   ```

3. Configure the WLAN for central switching.

   Example

   ```
   Device config-wireless-policy)# central switching
   ```

4. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Central switching configuration is applied, and data from devices is centrally processed in FlexConnect mode.

Configure an access point for FlexConnect

Configure an AP for FlexConnect.

For more information, see *Configuring a Site Tag (CLI)* topic in New Configuration Model chapter.

Configure an access point for local authentication on a WLAN (GUI)

Configure an AP for local authentication on a WLAN using GUI.

Configure an AP so that it uses local authentication for wireless LANs, enhancing the security and autonomy of network access control processes.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. In the **Policy Profile** page, select a policy profile name. The **Edit Policy Profile** window is displayed.
3. In the General tab, deselect **Central Authentication** check box.
4. Click **Update & Apply to Device**.

The AP is set up to authenticate users locally without relying on central authentication systems, providing secure and efficient network access verification.

Configure an access point for local authentication on a WLAN (CLI)

Configure an AP for local authentication on a WLAN using commands.

Configure an AP to use local authentication on a WLAN to enhance security control at the network edge.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile
   policy rr-xyz-policy-1
   ```

3. Configure the WLAN for local authentication.

Example

```
Device(config-wireless-policy)# no central authentication
```

4. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The AP is configured to authenticate WLAN users locally, bypassing central authentication mechanisms.

Connect client devices to WLANs

Connect client devices to WLANs.

A client device connection to a WLAN is a profile creation process that

- allows client devices to connect to wireless networks
- requires specific authentication methods, and
- assigns IP addresses upon successful authentication.

Additional Reference Information

Refer to the instructions for your client device to create profiles to connect to the WLANs you created. These instructions are specified in the Configuring the vEWLC for FlexConnect document.

Example Scenarios:

1. Employee WLAN: Create a client profile that uses WPA or WPA2 with PEAP-MSCHAPV2 authentication. After the client is authenticated, the management VLAN of the embedded controller assigns an IP address to the client.
2. Local-Employee WLAN: Create a client profile that uses WPA or WPA2 authentication. After the client is authenticated, the client is allotted an IP address by VLAN 101 on the local switch.
3. Guest-Central WLAN: Create a client profile that uses open authentication. After the client is authenticated, the client is allocated an IP address by VLAN 101 on the network local to the access point. After the client connects, a local user can enter any HTTP address in the web browser. The user is automatically directed to the controller to complete the web authentication process. When the web login window appears, the user should enter the username and password.

> **Note**
>
> Ensure that the authentication settings are configured correctly for each client profile.

FlexConnect ethernet fallback

FlexConnect Ethernet Fallback details.

A FlexConnect Ethernet Fallback is a configuration feature that

- allows the AP to shut down its radio when the Ethernet link is non-operational

- enables the AP to set its radio back to operational state when the Ethernet link is restored, and
- operates independently of the AP being in connected or standalone mode.

To prevent radios from flapping when there is Ethernet interface instability, a configurable delay timer is provided.

Configure FlexConnect ethernet fallback (CLI)

Configure FlexConnect ethernet fallback using commands.

Use CLI to configure the FlexConnect Ethernet fallback on specific APs to ensure network reliability in case of port failover.

Before you begin

This feature is not applicable to APs with multiple ports.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless flex profile and enter wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex test
   ```

3. Enable radio interface shutdown.

   Example

   ```
   Device(config-wireless-flex-profile)# fallback-radio-shut
   ```

4. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

5. Optional: Display detailed information about the selected profile.

   Example

   ```
   Device# show wireless profile flex detailed test
   ```

The FlexConnect Ethernet fallback is configured, ensuring that the radio interface shuts down during Ethernet failure, maintaining network continuity.

Configure FlexConnect AP local authentication (GUI)

Configure Flex AP local authentication using the GUI interface.

Configure the local authentication settings on a FlexConnect AP using the GUI to enable authentication and client handling directly on the AP.

Use these steps to configure FlexConnect AP local authentication:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. In the **Flex** page, click the name of the **Flex Profile** or click **Add** to create a new one.
3. In the **Add/Edit Flex Profile** window, click the **Local Authentication** tab.

   When you enable local authentication and association on the Access Point with Flex mode, these outcomes occur:

   - AP handles the authentication.
   - AP handles the rejection of client joins (in Mobility).

   > **Note**
   >
   > You will not receive updated statistics from the controller when the AP rejects client associations.

4. Choose the server group from the **RADIUS Server Group** drop-down list.
5. Use the **Local Accounting Radius Server Group** drop-down to select the RADIUS server group.
6. Check the **Local Client Roaming** check box to enable client roaming.
7. Choose the profile from the **EAP Fast Profile** drop-down list.
8. Choose to enable or disable these:

   - **LEAP:** Lightweight Extensible Authentication Protocol (LEAP) is an 802.1X authentication type for wireless LANs and supports strong mutual authentication between the client and a RADIUS server using a logon password as the shared secret. It provides dynamic per-user, per-session encryption keys.
   - **PEAP:** Protected Extensible Authentication Protocol (PEAP) is a protocol that encapsulates the Extensible Authentication Protocol (EAP) within an encrypted and authenticated Transport Layer Security (TLS) tunnel.
   - **TLS:** Transport Layer Security (TLS) is a cryptographic protocol that provides communications security over a computer network.
   - **RADIUS:** Remote Authentication Dial-In User Service (RADIUS) is a networking protocol that provides centralized Authentication, Authorization, and Accounting (AAA or Triple A) management for users who connect and use a network service.

9. In the **Users** section, click **Add**.
10. Enter username and password details and click **Save**.
11. Click **Save & Apply to Device**.

The AP is configured to handle local authentication requests, enabling improved client management.

Configure FlexConnect access point local authentication

Flex AP local authentication using commands.

You enable FlexConnect APs local authentication, allowing user authentication directly at the AP level using RADIUS profiles and methods.

> **Note**
>
> The Cisco Catalyst 9800 Series Wireless Controller + FlexConnect local authentication + AP acting as RADIUS are not supported on Cisco COS and IOS APs.

Procedure

1. Create a AAA authentication model.

   Example

   ```
   Device(config)# aaa new-model
   ```

2. Send session ID information from the RADIUS group for a given call.

   Example

   ```
   Device(config)# aaa session-id common
   ```

3. Enable system authorization control for the RADIUS group.

   Example

   ```
   Device(config)# dot1x system-auth-control
   ```

4. Create an EAP profile.

   Example

   ```
   Device(config)# eap profile aplocal-test
   ```

5. Configure the FAST method on the profile.

   Example

   ```
   Device(config-eap-profile)# method fast
   ```

6. Return to configuration mode.

   Example

   ```
   Device(config-radius-server)# exit
   ```

7. Configure the flex policy.

Example

```
Device(config)# wireless profile flex default-flex-profile
```

8. Configure EAP-FAST profile details.

Example

```
Device(config-wireless-flex-profile)# local-auth ap eap-fast aplocal-test
```

9. Configure LEAP method.

Example

```
Device(config-wireless-flex-profile)# local-auth ap leap
```

10. Configure the PEAP method.

Example

```
Device(config-wireless-flex-profile)# local-auth ap peap
```

11. Configure DHCP broadcast for locally switched clients.

Example

```
Device(config-wireless-flex-profile)# dhcp broadcast
```

12. Configure username and password.

Example

```
Device(config-wireless-flex-profile)# local-auth ap username username password
```

13. Configure another username and password.

Example

```
Device(config-wireless-flex-profile)# local-auth ap username username password
```

14. Return to configuration mode.

Example

```
Device(config-wireless-flex-profile)# exit
```

15. Configure profile policy.

Example

```
Device(config)# wireless profile policy default-policy-profile
```

16. Disable the policy profile.

Example

```
Device(config-wireless-policy)# shutdown
```

17. Disable central authentication.

Example

```
Device(config)# no central authentication
```

18. Configure VLAN name or VLAN ID.

Example

```
Device(config)# vlan-id 54
```

19. Enable the configuration.

Example

```
Device(config)# no shutdown
```

You can now authenticate users locally with FlexConnect APs by using specified EAP methods and profiles, operating under defined policy configurations.

Configure FlexConnect access point local authentication with external RADIUS server

FlexConnect access Point local authentication with external radius server using commands.

Set up local authentication on a FlexConnect access point using an external RADIUS server.

In this mode, an AP handles client authentication and switches client data packets locally. This state is valid in standalone mode and connected mode.

Use these steps to create and configure FlexConnect AP local authentication with a RADIUS server:

Procedure

---

1. Create a AAA authentication model.

Example

```
Device(config)# aaa new-model
```

2. Send session ID information from the RADIUS group for a given call.

Example

```
Device(config)# aaa session-id common
```

3. Enable the system authorization control for the RADIUS group.

Example

```
Device(config)# dot1x system-auth-control
```

4. Specify the RADIUS server name.

Example

```
Device(config)# radius server Test-SERVER1
```

> **Note**
>
> To authenticate clients with freeradius over RADSEC, you should generate an RSA key longer than 1024 bit. Use the **crypto key generate rsa general-keys exportable label** *name* command to achieve this.
>
> Do not configure **key-wrap** option under the radius server and radius server group, as it may lead to clients getting stuck in authentication state.

5. Specify the primary RADIUS server parameters.

Example

```
Device(config-radius-server)# address ipv4 ip-address address auth-port
port-number acct-port port-number
```

```
Device(config-radius-server)# address ipv6 ip-address address auth-port
port-number acct-port port-number
```

6. Specify the authentication and encryption key used between the device and the RADIUS daemon running on the RADIUS server.

Example

```
Device(config-radius-server)# key test123
```

> **Note**
>
> The maximum number of characters allowed for the shared secret is 63.

7. Specify the RADIUS server name.

Example

```
Device(config)# radius server Test-SERVER2
```

8. Specify the secondary RADIUS server parameters.

Example

```
Device(config-radius-server)# address ipv4 124.3.52.62 auth-port 1112 acct-port
 1113
```

```
Device(config-radius-server)# address ipv6 2001:DB8:0:21::15 auth-port 1812
acct-port 1813
```

9. Specify the authentication and encryption key used between the device and the RADIUS daemon running on the RADIUS server.

   Example

   ```
   Device(config-radius-server)# key test113
   ```

10. Return to configuration mode.

    Example

    ```
    Device(config-radius-server)# exit
    ```

11. Create a RADIUS server group identification.

    Example

    ```
    Device(config)# aaa group server radius aaa_group_name
    ```

    Note

    server-group refers to the server group name. The valid range is from 1 to 32 alphanumeric characters.

12. Specify the RADIUS server name.

    Example

    ```
    Device(config)# radius server Test-SERVER1
    ```

13. Specify the RADIUS server name.

    Example

    ```
    Device(config-radius-server)# radius server Test-SERVER2
    ```

14. Exit from RADIUS server configuration mode.

    Example

    ```
    Device(config-radius-server)# exit
    ```

15. Create a new flex policy.

Example

```
Device(config)# wireless profile flex default-flex-profile
```

16. Configure the authentication server group name.

Example

```
Device(config-wireless-flex-profile)# local-auth radius-server-group
aaa_group_name
```

17. Return to configuration mode.

Example

```
Device(config-wireless-flex-profile)# exit
```

18. Configure a WLAN policy profile.

Example

```
Device(config)# wireless profile policy default-policy-profile
```

19. Disable a policy profile.

Example

```
Device(config-wireless-policy)# shutdown
```

20. Disable central authentication.

Example

```
Device(config-wireless-policy)# no central authentication
```

21. Configure a VLAN name or VLAN Id.

Example

```
Device(config-wireless-policy)# vlan-id 54
```

22. Enable the configuration.

Example

```
Device(config-wireless-policy)# no shutdown
```

The FlexConnect AP is now set up for local authentication using the specified RADIUS server parameters.

Configuration example: FlexConnect with central and local authentication

FlexConnect with central and local authentication configuration example.

To see a configuration example on how to configure a controller for FlexConnect central and local authentication, refer to FlexConnect Configuration with Central and Local Authentication on Catalyst 9800 Wireless Controllers.

NAT-PAT functionalities in FlexConnect

Explains NAT-PAT implementation for FlexConnect, outlining procedures for WLAN and remote LAN setup, wireless profile and policy configuration, site tag deployment, and mapping policy and site tags to access points using both GUI and CLI interfaces.

NAT-PAT for FlexConnect is a networking function that:

- enables the use of a central DHCP server for assigning IP addresses to clients across remote sites
- involves an AP translating client traffic by replacing the private IP address with its own public IP address, and
- supports efficient management of IP address allocation.

If implementing NAT and PAT for flexibly managed networks, enable local switching and configure central DHCP. When ensuring DHCP service, use the **ipv4 dhcp required** command.

Create a WLAN

Create a WLAN using commands.

Configure and enable a WLAN using command line inputs, ensuring it is active and ready for use.

Use these steps to create a WLAN.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration sub-mode.

   Example

   ```
   Device(config)# wlan wlan-demo 1 ssid-demo
   ```

   - *wlan-name*–Enter the profile name. The range is from 1 to 32 alphanumeric characters.
   - *wlan-id*–Enter the WLAN ID. The range is from 1 to 512.
   - *SSID-name*–Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

> **Note**
>
> If you have already configured a WLAN, use the *wlan wlan-name* command.

3. Shut down the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

4. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is successfully configured and activated, allowing devices to connect using the specified SSID.

Configure a wireless profile policy and NAT-PAT (GUI)

Configure a wireless profile policy and NAT-PAT using GUI.

Define and apply a wireless profile policy and NAT-PAT settings using GUI.

Procedure

1. Navigate to **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add** to create a new policy.
3. In the **General** tab, enter the **Name** of the policy.
4. Disable the **Central Switching** toggle button.
5. Enable the **Central DHCP** toggle button.
6. Enable the **Flex NAT/PAT** toggle button.
7. In the **Advanced** tab, under the **DHCP** Settings, check the **IPv4 DHCP Required** check box.
8. Apply the configuration by selecting **Apply to Device**.

The configuration of the wireless profile policy and NAT-PAT settings is complete.

Configure a wireless profile policy and NAT-PAT (CLI)

Configure a wireless profile policy and NAT-PAT using commands.

Configure a wireless profile policy and enable NAT-PAT settings for a device using CLI.

Use the steps here to configure a wireless profile policy and NAT-PAT.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the policy profile for NAT.

   Example

   ```
   Device(config)# wireless profile policy nat-enabled-policy
   ```

3. Configure the WLAN for local switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

4. Configure the DHCP parameters for WLAN.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp required
   ```

5. Configure the central DHCP for locally switched clients.

   Example

   ```
   Device(config-wireless-policy)# central dhcp
   ```

6. Enable NAT-PAT.

   Example

   ```
   Device(config-wireless-policy)# flex nat-pat
   ```

7. Enable policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

Wireless profile policy is configured and NAT-PAT is activated, which facilitates network traffic management and enables efficient packet handling on your device.

Map a WLAN to a policy profile (CLI)

Map a WLAN to a Policy Profile using commands.

Enable seamless network management by mapping a WLAN to a designated policy profile through CLI.

Use these steps to map a WLAN to a policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config)# wireless tag policy demo-tag
   ```

3. Map a policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan wlan-demo policy nat-enabled-policy
   ```

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-policy-tag)# end
   ```

WLAN is mapped to the specified policy profile, ensuring the application of the required network policies.

Configure a site tag

Configure a site tag using commands.

Configure a site tag to enhance management and control of your wireless network.

Use these steps to configure a site tag:

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a site tag and enter site tag configuration mode.

Example

```
Device(config)# wireless tag site flex-site
```

3. Move the AP to FlexConnect mode.

Example

```
Device(config-site-tag)# no local-site
```

4. Return to privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

The FlexConnect mode is configured onto the assigned AP, enhancing network flexibility and management.

Attach policy and site tags to an access point (GUI)

Attach a policy tag and a site tag to an AP using GUI.

This task allows you to efficiently organize and manage access points by assigning specific policy and site tags through GUI.

Use these steps to assign policy and site tags to an AP using GUI:

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. Click the **Access Point** name.
3. Go to the **Tags** section.
4. Choose the **Policy Tag** from the **Policy** drop-down list.
5. Choose the **Site Tag** from the **Site** drop-down list.
6. Click **Update and Apply to Device**.

The AP has the designated policy and site tags, ensuring it operates under defined network conditions and policy settings.

Attach a policy tag and a site tag to an access point (CLI)

Attach a policy tag and a site tag to an AP using commands.

Apply network policy and site tags to an AP using commands.

Use these steps to attach a policy tag and a site tag to an AP:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure APs and enter ap-tag configuration mode.

   Example

   ```
   Device(config)# ap F866.F267.7DFB
   ```

3. Map the policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag demo-tag
   ```

4. Map the site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag flex-site
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

The AP has the specified policy and site tags applied, ready for network reconfiguration.

Split tunneling for FlexConnect

Describes split tunneling capabilities for FlexConnect, detailing restrictions, access control list definition, wireless profile and policy configuration, WLAN creation, mapping WLANs to policy profiles, site tag assignment, and procedures for deploying split tunneling on WLANs and remote LANs.

Split tunneling is a network feature that:

- minimizes unnecessary bandwidth consumption on WAN links
- allows traffic classification based on packet contents for local switching, and
- ensures efficient routing of data by distinguishing between local and central switching requirements.

If a client connects over a WAN link associated with a centrally switched WLAN, traffic intended for a device present in the local site is typically sent over CAPWAP to the controller, then back to the local site over CAPWAP or via some off-band connectivity. This consumes WAN link bandwidth unnecessarily. The split tunneling feature mitigates this by classifying client traffic based on packet contents. Matching packets are locally switched, while the rest are centrally switched.

Configuration details

To configure local split tunneling on an AP, ensure that you have enabled DHCP Required on the policy profile using the **ipv4 dhcp required** command. This ensures the client associating with the split WLAN performs DHCP.

Restriction: split tunneling for FlexConnect

Restriction for split tunneling for FlexConnect

- Ensure Apple iOS clients receive option 6 (DNS) in the DHCP offer for split tunneling to function correctly.
- VLAN-based central switching for FlexConnect in auto-anchor deployment is not supported.
- You cannot use split tunneling with RLAN clients. When the **split-tunnel** option is enabled on RLAN, traffic denied by the split tunnel ACL is not translated based on the IP address, instead the traffic is sent back to the controller through CAPWAP.
- Do not configure URL filters with wildcard URLs such as * and ".".

Configure Split Tunneling for a WLAN or Remote LAN

-

Define an access control list for split tunneling (GUI)

Define an ACL for Split Tunneling using GUI.

Define an ACL for split tunneling.

Use these steps to define an ACL for split tunneling in the GUI.

Procedure

1. Choose **Configuration** > **Security** > **ACL**.
2. Click **Add**.
3. In the **Add ACL Setup** dialog box, enter the **ACL Name**.
4. Choose the ACL type from the **ACL Type** drop-down list.
5. Under the **Rules** settings, enter the **Sequence** number and choose the **Action** as either **permit** or **deny**.
6. Choose the required source type from the **Source Type** drop-down list.

If...	Then...
Source type is **Host**	Enter the **Host Name/IP**
Source type is **Network**	Specify the **Source IP** address and **Source Wildcard** mask

7. Check the **Log** check box if you want the logs.
8. Click **Add**.
9. Add the rest of the rules and click **Apply to Device**.

The ACL is defined and applied to the specified device for the purpose of split tunneling. You can view the rules in the device's ACL configuration.

Define an ACL for split tunneling (CLI)

Define an ACL for split tunneling using commands.

Define an ACL for split tunneling to manage traffic effectively between local and remote networks, improving network performance and security.

Use these steps to create an ACL for split tunneling.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Define an extended IPv4 access list using a name, and enter access-list configuration mode.

   Example

   ```
   Device(config)# ip access-list extended split_mac_acl
   ```

3. Allow the traffic to switch centrally.

   Example

   ```
   Device(config-ext-nacl)# deny ip any host 9.9.2.21
   ```

4. Allow the traffic to switch locally.

   Example

   ```
   Device(config-ext-nacl)# permit ip any any
   ```

5. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-ext-nacl)# end
   ```

The ACL selectively allows local or central switching of network traffic, enhancing performance and security management.

Link an ACL policy to the defined ACL (CLI)

Link an ACL policy to the defined ACL using commands.

This task provides the steps necessary to associate an ACL policy with a defined ACL, enhancing the ability to manage and control network traffic according to specified security parameters.

Use these steps to link an ACL policy to the defined ACL.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the Flex profile and enter flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex-profile
   ```

3. Configure an ACL policy for the defined ACL.

   Example

   ```
   Device(config-wireless-flex-profile)# acl-policy acl-policy-name
   ```

4. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

The ACL policy is linked, allowing the defined ACL to enforce specified access control rules on network traffic.

Create a WLAN

Create a WLAN using commands.

Configure and enable a WLAN using command line inputs, ensuring it is active and ready for use.

Use these steps to create a WLAN.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify the WLAN name and ID

   Example

   ```
   Device(config)# wlan wlan-demo 1 ssid-demo
   ```

   - *wlan-name*–Enter the profile name. The range is from 1 to 32 alphanumeric characters.
   - *wlan-id*–Enter the WLAN ID. The range is from 1 to 512.

- *SSID-name*–Enter the Service Set Identifier (SSID) for this WLAN. If the SSID is not specified, the WLAN profile name is set as the SSID.

3. Shut down the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

4. Return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

The WLAN is successfully configured and activated, allowing devices to connect using the specified SSID.

Configure a wireless profile policy and a split MAC ACL name (GUI)

Configure a Wireless Profile Policy and a Split MAC ACL Name using GUI.

Configure a wireless profile policy and apply a split MAC ACL name to optimize resource allocation and traffic management.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add**.
3. In the **General** tab, enter the **Name** of the policy.
4. Enable the **Central Switching** toggle button.
5. Enable the **Central DHCP** toggle button.
6. In the **Advanced** tab, under the **DHCP** settings, check the **IPv4 DHCP Required** check box and enter the **DHCP Server IP Address**.
7. Under the **WLAN Flex Policy** settings, choose the split MAC ACL from the **Split MAC ACL** drop-down list.
8. Click **Apply to Device**.

The wireless profile policy and split MAC ACL name are configured and applied to the device, ensuring coordinated network resource management.

Configure a wireless profile policy and a split MAC ACL name

Configure a wireless profile policy and a split MAC ACL name using commands.

You will establish a secure wireless network environment by configuring a wireless profile policy and a split MAC ACL name.

Use these steps to configure a wireless profile policy and a split MAC ACL name:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN policy profile and enter wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy split-tunnel-enabled-policy
```

3. Configure a split MAC ACL name.

Example

```
Device(config-wireless-policy)# flex split-mac-acl split_mac_acl
```

> **Note**
>
> You must use the same ACL name for linking the flex and the policy profile.

4. Configure WLAN for central switching.

Example

```
Device(config-wireless-policy)# central switching
```

5. Enable central DHCP for centrally switched clients.

Example

```
Device(config-wireless-policy)# central dhcp
```

6. Configure the DHCP parameters for a WLAN.

Example

```
Device(config-wireless-policy)# ipv4 dhcp required
```

7. Optional: Configure the override IP address of the DHCP server.

Example

```
Device(config-wireless-policy)# ipv4 dhcp server 9.1.0.100
```

8. Enable a policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

The wireless profile policy is active with a configured split MAC ACL name, ensuring traffic is managed according to the defined policy guidelines.

Map a WLAN to a policy profile (GUI)

Map a WLAN to a policy profile using GUI.

Map a WLAN to its associated policy profile to ensure network policy configurations are enforced.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. Click **Add**.
3. Enter the **Name** of the Tag Policy.
4. Under **WLAN-POLICY Maps** tab, click **Add**.
5. Choose the WLAN Profile from the **WLAN Profile** drop-down list.
6. Choose the Policy Profile from the **Policy Profile** drop-down list.
7. Click the **Tick** Icon.
8. Click **Apply to Device**.

The WLAN is mapped to the desired policy profile by the system, and configuration is enforced on the device.

Map WLAN to a policy profile

Map a WLAN to a policy profile using commands.

Map a WLAN to a policy profile to enhance network management by applying specific policies to WLAN configurations.

Use these steps to map WLAN to a policy profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config)# wireless tag policy split-tunnel-enabled-tag
   ```

3. Map a policy profile to a WLAN profile.

Example

```
Device(config-policy-tag)# wlan wlan-demo policy split-tunnel-enabled-policy
```

4. Return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

The WLAN is associated with the policy profile, ensuring compliance with network policies for connected devices.

Configure a site tag

Configure a site tag using commands.

Configure a site tag for split tunneling, optimizing network performance through selective traffic routing.

Use the steps to configure a site tag:

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a site tag and enter site tag configuration mode.

Example

```
Device(config)# wireless tag site flex-site
```

3. Ensure the local site is not configured on the site tag.

Example

```
Device(config-site-tag)# no local-site
```

4. Configure a flex profile.

Example

```
Device(config-site-tag)# flex-profile flex-profile
```

5. Return to privileged EXEC mode.

Example

```
Device(config-site-tag)# end
```

The site tag for split tunneling is successfully configured, providing optimized network traffic routing.

Attach policy and site tags to an AP

Attach policy and site tags to your AP using commands.

Use this task to configure policy and site tags on your AP using CLI.

Use these steps to attach a policy tag and site tag to your AP.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a Cisco AP and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap 188b.9dbe.6eac
   ```

3. Map a policy tag to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag split-tunnel-enabled-tag
   ```

4. Map a site tag to the AP.

   Example

   ```
   Device(config-ap-tag)# site-tag flex-site
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

The policy and site tags configure the AP with designated network management settings. Verify the mapping by checking the APs configuration status in the system.

VLAN-based central switching for FlexConnect

Details VLAN-based central switching in FlexConnect environments, providing instructions for GUI and CLI configuration to support centralized VLAN switching for wireless deployments.

VLAN-based central switching for FlexConnect is a network configuration method that

- enables traffic redirection to the controller when a VLAN is not defined locally
- supports local switching if the VLAN is present in the AP's database, and
- requires VLANs to be defined on the controller for proper functionality.

Expanded explanation

- In FlexConnect local switching, if the VLAN definition is not available in an AP, the corresponding client does not pass traffic. This scenario is applicable when the AAA server returns the VLAN as part of client authentication.
- When a WLAN is locally switched in FlexConnect and a VLAN is configured on the AP side, the traffic is switched locally. When a VLAN is not defined in an AP, the VLAN drops the packet.

Special considerations

- The controller forwards the traffic to its corresponding VLAN.
- Ensure that VLAN is defined on the controller for VLAN-based central switching.
- VLAN-based central switching is not supported by mac filter.
- For local switching, ensure that VLAN is defined on both the policy profile and FlexConnect profile.
- VLAN-based central switching with central web authentication enabled in Flex profile is not supported.

Restriction on multiple policy profiles and VLAN behavior

Restriction

If you add multiple policy profiles to a policy tag that uses a VLAN-based, central-switching SSID, do not configure the central switch VLAN in any profile. Avoid using the VLAN ID, and do not define a VLAN name in the Flex profile. Otherwise, the system switches all traffic for that VLAN locally

The reason for this behavior: If the VLAN is present in the access point (AP) database, the system overrides central switching and switches client traffic locally

Configure VLAN-based central switching (GUI)

Configure VLAN-based central switching using GUI.

Enable VLAN-based central switching on a policy profile using the GUI to manage network traffic effectively.

Use these steps to configure VLAN-based central switching.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click the name of the policy profile.

3. In the **Edit Policy Profile** window, perform these tasks:
   - Set **Central Switching** to **Disabled** state.
   - Set **Central DHCP** to **Disabled** state.
   - Set **Central Authentication** to **Enabled** state.
4. Click the **Advanced** tab.
5. Under **AAA Policy**, check the **Allow AAA Override** check box to enable AAA override.
6. Under **WLAN Flex Policy**, check the **VLAN Central Switching** check box to enable VLAN-based central switching on the policy profile.
7. Click **Update & Apply to Device**.

VLAN-based central switching is configured in the policy profile, enabling centralized network traffic management.

Configure VLAN-based central switching (CLI)

Configure VLAN-based central switching using commands.

Configure VLAN-based central switching in a wireless network environment using CLI to enable efficient data forwarding and management.

Use these steps to configure VLAN-based central switching.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

3. Configure a WLAN for local switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

4. Configure local DHCP mode, with DHCP being performed in an AP.

   Example

   ```
   Device(config-wireless-policy)# no central dhcp
   ```

5. Configure a WLAN for central authentication.

Example

```
Device(config-wireless-policy)# central authentication
```

6. Configure AAA policy override.

   Example

   ```
   Device(config-wireless-policy)# aaa-override
   ```

7. Configure VLAN-based central switching.

   Example

   ```
   Device(config-wireless-policy)# flex vlan-central-switching
   ```

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

9. Optional: Display detailed information of the policy profile.

   Example

   ```
   Device# show wireless profile policy detailed default-policy-profile
   ```

VLAN-based central-switching is established, optimizing network traffic flow and centralizing control.

OfficeExtend AP for FlexConnect

Outlines features and best practices for OEAP in FlexConnect, including configuration and disabling of OEAPs, support for personal SSIDs, related configuration tasks, and examples of viewing OfficeExtend settings and personal SSID management.

A Cisco OfficeExtend Access Point (OEAP) is a type of wireless access point that

- extends the corporate WLAN over the Internet to remote locations
- ensures secure communication between the controller and access point through DTLS encryption, and
- provides users with a seamless experience comparable to being at a corporate office.

Datagram Transport Layer Security (DTLS) encryption is utilized between the access point and the controller to maintain the highest level of communication security.

Configure OfficeExtend AP

Configure OEAP using commands.

Enable and configure OEAP mode on FlexConnect APs.

Use these steps to configure OEAP.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless flex profile and enter wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex test
   ```

3. Enable the OEAP mode for a FlexConnect AP.

   Example

   ```
   Device(config-wireless-flex-profile)# office-extend
   ```

4. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

   Note

   After creating a flex profile, ensure that OEAP is in flex connect mode and mapped to its corresponding site tag.

   OfficeExtend is disabled by default. To clear the access point's configuration and return it to the factory-defaults, use the **clear ap config** *cisco-ap* command.

The OEAP is configured and enabled in FlexConnect mode, ready for deployment in a remote office setup.

Disable OfficeExtend AP

Disable OEAP using commands.

Disabling the OEAP mode on a specific FlexConnect AP to optimize wireless network management and security.

Use these steps to disable an OEAP.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a wireless flex profile and enter wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex test
   ```

3. Disable OfficeExtend AP mode for a FlexConnect AP.

   Example

   ```
   Device(config-wireless-flex-profile)# no office-extend
   ```

4. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

The configured FlexConnect AP is no longer operating in OEAP mode.

Best practices for OfficeExtend AP for FlexConnect

- Preconfigure your controller IP for a zero-touch deployment with OEAP. Configure the local SSID from the AP, allowing other home users to connect using the same AP.
- In releases prior to Cisco IOS XE 17.3.2, when an AP is converted to OEAP, the local DHCP server on the AP is enabled by default. If the DHCP server on the home router has a similar configuration, a network conflict occurs, preventing the AP from rejoining the controller. Change the default DHCP server to resolve this.
- For OEAP, when configuration changes are made from the OEAP GUI to Radio Status, Radio Interface Status, 802.11 n-mode, 802.11 ac-mode, Bandwidth, or Channel Selection (2.4 GHz or 5 GHz), restart CAPWAP to synchronize configurations between the AP and the controller. During this interval, the AP GUI may not respond; it will resume functionality once the AP rejoins the controller. Wait about 1–2 minutes for the AP to rejoin the controller before making further changes from the OEAP GUI.
- In OEAP, if the OEAP local DHCP server is enabled and the user configures DNS IP from OEAP GUI, the wireless and wired clients connected to Cisco OEAP will receive that IP as DNS server IP in DHCP ACK.

OEAP personal SSID support

OEAP Personal SSID Support details.

A personal SSID is a feature of the Cisco OEAP that

- enables local home clients to connect using personal network identifiers
- allows leveraging existing OEAP infrastructure for local connectivity, and
- supports standard security protocols for safe operation.

Additional information

- OEAP supports the enabling or disabling of personal SSID.
- Datagram Transport Layer Security (DTLS) encryption can be enabled or disabled between an access point and the controller.
- Rogue detection can be configured using the controls available on the AP profile page in the GUI.
- The local network access and DTLS encryption are enabled by default.

> **Note**
>
> These configurations are applicable for OEAP or for APs in the OEAP mode.

Configure OEAP personal SSID (GUI)

Configure OEAP personal SSID using GUI.

Setup and configure OEAP personal SSID using GUI for enhanced local network access and security features on AP devices.

Use these steps to configure OEAP personal SSID.

Procedure

1. Choose **Configuration** > **AP Tags & Profiles** > **AP Join**.

   The **AP Join Profile** section displays all the AP Join profiles.

2. To edit the configuration details of an AP Join profile, select APs in the OEAP mode.

   The **Edit AP Join Profile** window is displayed.

3. In the **General** tab, under the **OfficeExtend AP Configuration** section, configure the following:

   Configure the options according to your requirements for local network access, data encryption, and rogue detection.

   Example

   ```
   Configuration settings include enabling Local Access, Link Encryption, and
   Rogue Detection.
   ```

   a) Check the **Local Access** check box to enable the local network. By default, **Local Access** is enabled. After the AP joins the controller using AP join profile where local access is enabled, the AP will not broadcast the default personal SSID. Since the local access is enabled, you can login to the AP GUI and configure the personal SSID.
   b) Check the **Link Encryption** check box to enable data DTLS. By default, **Link Encryption** is enabled.
   c) Check the **Rogue Detection** check box to enable rogue detection. Rogue detection is disabled by default for OfficeExtend APs because these APs, deployed in a home environment, are likely to detect a large number of rogue devices.

The AP is configured with specific OEAP personal SSID settings for local access, encryption, and detection capabilities, ensuring secure and tailored network operations.

Configure OfficeExtend AP personal SSID (CLI)

Configure OEAP personal SSID using commands.

Configure a personal SSID on an OEAP using CLI to enable local access and encryption features.

Use these steps to configure OEAP personal SSID using CLI:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

3. Enable the local access to AP.

   Example

   ```
   Device(config-ap-profile)# oeap local-access
   ```

   Local access consists of local AP GUI, LAN ports, and personal SSID. The **no** form of this command disables the feature. If the local access is disabled, you will not be able to access the AP GUI, the local LAN port will be disabled, and personal SSID will not be broadcasted.

4. Enable DTLS encryption for OEAP APs or APs moving to the OEAP mode.

   Example

   ```
   Device(config-ap-profile)# oeap link-encryption
   ```

   The **no** form of this command disables the feature. This feature is enabled by default.

5. Enable OEAP DTLS encryption in the AP profile configuration mode.

   Example

   ```
   Device(config-ap-profile)# no oeap rogue-detection
   ```

   This feature is disabled by default.

The OEAP personal SSID is configured with local access and DTLS encryption enabled, allowing secure connection and management of the AP through the local interface.

View OEAP personal SSID configuration

View OEAP personal SSID configuration.

To view the OEAP personal SSID configuration, run this command:

```
Device# show ap profile name default-ap-profile detailed
.
.
.
OEAP Mode Config
Link Encryption : ENABLED
Rogue Detection : DISABLED
Local Access : ENABLED
```

Clearing personal SSID from an OfficeExtend access point

Clear Personal SSID from an OEAP.

To clear the personal SSID from an access point, run this command:

ap name *Cisco_AP*clear-personal-ssid

Example: viewing OfficeExtend configuration

Viewing OfficeExtend Configuration example.

This example displays an OfficeExtend configuration:

```
Device# show ap config general

Cisco AP Name   : ap_name
=================================================

Cisco AP Identifier                              : 70db.986d.a860

Proxy address resolution protocol

Explains Proxy-ARP functionality in FlexConnect, providing instructions for enabling Proxy ARP on FlexConnect APs through GUI and CLI workflows.

A proxy address resolution protocol (Proxy ARP) is a method that

- enables learning about MAC addresses through a proxy device
- allows APs to act on behalf of clients by responding to ARP requests, and
- reduces airtime usage by handling ARP requests via controllers rather than clients.

Additional information

The AP functions as an ARP proxy to respond to ARP requests on behalf of clients, minimizing unnecessary air traffic by preventing requests from reaching clients directly when Proxy ARP is enabled. APs that don't own the destination client drop ARP requests unless ARP caching is disabled, in which case APs bridge requests, potentially increasing wireless broadcasts.

Enable proxy ARP for FlexConnect access points (GUI)

Enable Proxy ARP for FlexConnect APs using GUI.

Enable Proxy ARP for FlexConnect APs through the GUI.

Use these steps to enable proxy ARP for FlexConnect APs.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. Click **Add**.
3. In the **General** tab, enter the **Name** of the Flex Profile and check the **ARP Caching** check box. The name can be ASCII characters from 32 to 126, without leading and trailing spaces.
4. Click **Apply to Device**.

The AP handles ARP requests efficiently, improving network performance through enabled proxy ARP.

Enable proxy ARP for FlexConnect access points (CLI)

Enable Proxy ARP for FlexConnect APs using commands.

Configure proxy ARP for FlexConnect APs using the CLI.

Use these steps to configure proxy ARP for FlexConnect APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter wireless flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex-test
   ```

3. Enable ARP caching.

   Example

   ```
   Device(config-wireless-flex-profile)# arp-caching
   ```

   Use the **no arp-caching** command to disable ARP caching.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

5. Display ARP configuration information.

   Example

   ```
   Device# show running-config | section wireless profile flex
   ```

6. Optional: Display detailed information of the flex profile.

   Example

   ```
   Device# show wireless profile flex detailed flex-test
   ```

7. Optional: Display ARP summary.

   Example

   ```
   Device# show arp summary
   ```

Proxy ARP is enabled for FlexConnect APs, allowing for more effective handling of ARP requests in a network setup.

Overlapping client IP address in flex deployment

Describes overlapping client IP scenarios in FlexConnect deployments, offering step-by-step procedures for enabling and verifying overlapping client IP addresses using both GUI and CLI, with verification references.

An overlapping client IP address in Flex deployment is a network configuration strategy that

- uses the same subnet configurations across multiple sites and branches
- includes local DHCP servers configured with identical subnets at each location, and
- identifies and manages multiple client sessions using the same IP address to prevent issues such as IP theft.

In Flex deployments, this strategy allows for cookie-cutter configurations across sites, simplifying network management by ensuring consistent settings.

Controllers in this setup detect duplicate IP usage among clients, categorizing such occurrences as IP theft. These clients are subsequently placed on a blocked list to maintain network security and integrity.

Enable overlapping client IP address in flex deployment (GUI)

Enable Overlapping Client IP Address in Flex Deployment using GUI.

Enable the setting for overlapping client IP addresses to optimize IP management in a Flex deployment.

Use these steps to enable overlapping client IP address in Flex deployment.

Procedure

1. Choose **Configuration > Tags & Profiles > Flex** and click **Add**.
2. On the **Add Flex Profile** window and **General** tab.
3. Check the **IP Overlap** checkbox to enable overlapping client IP address in Flex deployment.
4. Click **Apply to Device**.

Overlapping client IP addresses are now enabled in the Flex deployment. This allows efficient IP address management where different clients might share similar IP addresses.

Enable overlapping client IP address in flex deployment

Enable Overlapping Client IP Address in Flex Deployment using commands.

Enable overlapping client IP address assignment in a Flex deployment to enhance network segmentation and address allocation.

Use these steps to enable overlapping client IP addresses in a Flex deployment:

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a Flex profile and enter Flex profile configuration mode.

   Example

   ```
   Device(config)# wireless profile flex flex1
   ```

3. Enable overlapping client IP address in flex deployment.

   Example

   ```
   Device(config-wireless-flex-profile)# [no] ip overlap
   ```

   By default, the configuration is disabled.

Overlapping client IP addresses in a Flex deployment are now enabled, allowing for flexible IP management and improved network segmentation.

Verify overlapping client IP address in flex deployment (GUI)

Verify overlapping client IP address in flex deployment using GUI.

Verify the client statistics in the IP monitoring interface to ensure accurate data representation and maintain operational oversight.

Use these steps to verify the client statistics in IP monitoring.

Procedure

---

1. Choose **Monitoring** > **Wireless** > **Clients**
2. Click the client in the table to view properties and statistics for each client.
3. On the **Client** window and **General** tab, click **Client Statistics** tab to view the following details:
   - Number of bytes received from client
   - Number of bytes sent to client
   - Number of packets received from client
   - Number of packets sent to client
   - Number of policy errors
   - Radio signal strength indicator
   - Signal-to-noise ratio
   - IP - zone ID mapping
4. Click **OK**.

The verified client statistics are displayed confirming network performance adherence to set requirements.

Verify overlapping client IP address in flex deployment

Verify Overlapping Client IP Address in Flex Deployment using commands.

To verify if the overlapping client IP address in Flex deployment feature is enabled or not, use this command:

```
Device# show wireless profile flex detailed flex1
Fallback Radio shut            : DISABLED
ARP caching                    : ENABLED
Efficient Image Upgrade        : ENABLED
OfficeExtend AP                : DISABLED
Join min latency               : DISABLED
IP overlap status              : DISABLED
```

To view additional details about the overlapping client IP address in Flex deployment feature, use this command:

```
Device# show wireless device-tracking database ip

IP                                          ZONE-ID       STATE      DISCOVERY
   MAC
-------------------------------------------------------------------------------------------

  9.91.59.154                                 0x00000002  Reachable   IPv4
Packet 6038.e0dc.3182

    58ef.680d.c6c3
  2001:9:3:59:f9b5:3074:d0da:f93b            0x00000002  Reachable   IPv6 NDP
    58ef.680d.c6c3
  fe80::f9b5:3074:d0da:f93b                  0x80000001  Reachable   IPv6 NDP
    58ef.680d.c6c3
```

To view APs in various site tags, use this command:

```
Device# show ap tag summary
Number of APs: 5

AP Name AP Mac Site Tag Name Policy Tag Name RF Tag Name Misconfigured Tag
Source
-----------------------------------------------------------------------------------------------------
AP3802 70b3.17f6.37aa flex_ip_overlap-site-tag-auto-3
flex_ip_overlap_policy_tag_1 default-rf-tag No Static
AP-9117AX 0cd0.f894.0f8c default-site-tag default-policy-tag default-rf-tag
No Default
AP1852JJ9 38ed.18ca.2b48 flex_ip_overlap-site-tag-auto-2
flex_ip_overlap_policy_tag_2 default-rf-tag No Static
AP1852I 38ed.18cc.61c0 flex_ip_overlap-site-tag-auto-1
flex_ip_overlap_policy_tag_1 default-rf-tag No Static
AP1542JJ9 700f.6a84.1b30 flex_ip_overlap-site-tag-auto-2
flex_ip_overlap_policy_tag_2 default-rf-tag No Static
```

To view APs in FlexConnect mode, use this command:

```
Device# show ap status
AP Name     Status      Mode        Country
-------------------------------------------------------------------------
AP3802      Disabled   FlexConnect   IN
AP1852I     Enabled    FlexConnect   US
AP-9117AX   Enabled    FlexConnect   IN
AP1542JJ9   Disabled   FlexConnect   US
AP1852JJ9   Enabled    FlexConnect   US
```

Troubleshoot overlapping client IP address in flex deployment

To verify the WNCD instance for each of the APs, use this command:

```
Device# show wireless loadbalance ap affinity wncd 0
AP Mac          Discovery Timestamp    Join Timestamp          Tag
-------------------------------------------------------------------------------
0cd0.f894.0f8c   10/27/20 22:11:05    10/27/20 22:11:14    default-site-tag
38ed.18ca.2b48   10/27/20 22:06:09    10/27/20 22:06:19
flex_ip_overlap-site-tag-auto-2
700f.6a84.1b30   10/27/20 22:25:03    10/27/20 22:25:13
flex_ip_overlap-site-tag-auto-2
```

FlexConnect high scale mode

Describes FlexConnect site scaling capabilities, providing procedures for enabling PMK propagation via CLI to support scaling to higher numbers of APs per site tag.

A FlexConnect site capacity is a network feature that:

- scales up to accommodate 300 APs
- supports 3000 802.1x clients, and
- uses PMK caching to bypass EAP exchange during client roaming.
- When a client connects to an AP using an 802.1x authentication setup, the AP under the FlexConnect architecture stores the PMK from the EAP exchange.
- With PMK caching, subsequent connections from the same client bypass the EAP exchange, reducing authentication time.

Supporting information

- The PMK propagation feature is disabled by default.
- Until Cisco IOS XE 17.8.1, the wireless controller pushed the PMK cache to each FlexConnect AP at the same site for faster roaming.
- From Cisco IOS XE 17.8.1 onwards, the PMK cache is shared among FlexConnect APs at the same site for faster roaming.

Enable PMK propagation (CLI)

Enable PMK Propagation using commands.

Enable PMK propagation to facilitate seamless wireless client roaming by sharing PMK information among AP within a single site.

Use these steps to enable PMK propagation:

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create a FlexConnect profile.

Example

```
Device(config)# wireless profile flex test-flex-profile
```

3. Propagate PMK information to the other APs in the site.

Example

```
Device(config-wireless-flex-profile)# pmk propagate
```

> **Note**
>
> The PMK propagation feature is disabled by default.

PMK propagation is enabled, allowing APs to share PMK information within the site, which enhances wireless client mobility by reducing the latency typically associated with re-authentication.

Example

```
Device# configure terminal
Device(config)# wireless profile flex test-flex-profile
Device(config-wireless-flex-profile)# pmk propagate
```

Flex resilient with Flex and bridge modes

Explains Flex Resilient deployment with Flex and bridge mode APs, detailing configuration steps for Flex and mesh profiles, site tag and mesh associations, switch interface setup, AP attachment, and verification of resilient configurations.

A flex resilient system in flex and bridge modes is a network feature that

- operates within a configuration involving both flex and bridge mode APs
- allows the primary functionality of APs as mesh links between a root access point (RAP) and mesh access point (MAP), and
- ensures that the feature's operations are limited to flex and bridge mode APs.

Additional reference information

- Flex+Bridge Mode: A configuration mode combining the flexibility of standalone (local) management for APs with stable mesh network connectivity through root and mesh APs.
- Mesh Link Operation: Exists between RAP and MAP, allowing communication and bridging.

- Client Connectivity:
  - No new or disconnected clients can associate with a Mesh AP in flex+bridge mode.
  - Ongoing connections are maintained until a loss of the parent link for a child MAP.
- In a locally switching WLAN, the client traffic of a Flex+Bridge MAP is sent to the RAP's switchport.
- A child MAP that loses its parent connection cannot connect to a new parent without reacquiring a connection to the CAPWAP controller.
- The feature does not operate on non-Flex+Bridge mode APs.
- A new or disconnected wireless client cannot associate with a Mesh AP when in this mode.

Configure a flex profile (GUI)

Configure a flex profile using GUI.

Set up a flex profile to enhance network resilience and enable local authentication.

Use these steps to configure a flex profile using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Flex**.
2. Click a **Flex Profile Name**. The **Edit Flex Profile** dialog box appears.
3. Under the **General** tab, choose the **Flex Resilient** check box to enable the Flex Resilient feature.
4. Under the **VLAN** tab, choose the required VLANs.
5. (Optionally) Under the **Local Authentication** tab, choose the desired server group from the **Local Accounting RADIUS Server Group** drop-down list. Also, choose the **RADIUS** check box.
6. Click **Update & Apply to Device**.

The flex profile is successfully configured and updated in the system.

Configure a Flex profile (CLI)

Configure a Flex Profile using commands.

Configure a Flex Profile using commands on a network device to enable specific features and settings.

Use these steps to configure a flex profile using the CLI.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a flex profile and enters flex profile configuration mode using the **wireless profile flex** *flex-profile* command.

Example

```
Device(config)# wireless profile flex new-flex-profile
```

3. Enable ARP caching.

   Example

   ```
   Device(config-wireless-flex-profile)# arp-caching
   ```

4. Enable default parameters for the Flex profile using the **description** *description* command.

   Example

   ```
   Device(config-wireless-flex-profile)# description "new flex profile"
   ```

5. Configure native vlan-id information.

   Example

   ```
   Device(config-wireless-flex-profile)# native-vlan-id 2660
   ```

6. Enable the resilient feature.

   Example

   ```
   Device(config-wireless-flex-profile)# resilient
   ```

7. Configure VLAN name using the **vlan-name** *vlan_name* command.

   Example

   ```
   Device(config-wireless-flex-profile)# vlan-name VLAN2659
   ```

8. Configure the VLAN ID.

   Example

   ```
   Device(config-wireless-flex-profile)# vlan-id 2659
   ```

   The valid VLAN ID ranges from 1 to 4096.

9. Exit the configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

The Flex profile is configured on the network device with the specified settings and features.

Configure a site tag (CLI)

Configure a Site Tag using commands.

Configure a site tag on a network device to manage wireless networks efficiently and map APs to specific site tags.

Use these steps to configure a site tag using CLI.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a site tag and enter site tag configuration mode using the **wireless tag site** *site-name* command.

   Example

   ```
   Device(config)# wireless tag site new-flex-site
   ```

3. Configure a flex profile using the **flex-profile** *flex-profile-name* command.

   Example

   ```
   Device(config-site-tag)# flex-profile new-flex-profile
   ```

4. Remove **Local site** configured from the site tag.

   Example

   ```
   Device(config-site-tag)# no local-site
   ```

5. Map a site tag to an AP using the **site-tag** *site-tag-name* command.

   Example

   ```
   Device(config-site-tag)# site-tag new-flex-site
   ```

6. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-site-tag)# end
   ```

The site tag is configured and mapped to the specified AP, facilitating effective management of wireless networks within the defined site tag.

Configure a mesh profile (CLI)

Configure a mesh profile using commands.

Configure a mesh profile on a network device to enable communication between mesh nodes, ensuring VLAN awareness and connectivity management.

Use these steps to configure a mesh profile using CLI commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a mesh profile and enter the mesh profile configuration mode using the **wireless profile mesh** *profile-name* command.

   Example

   ```
   Device(config)# wireless profile mesh Mesh_Profile
   ```

3. Disable VLAN transparency to ensure that the bridge is VLAN aware.

   Example

   ```
   Device(config-wireless-profile-mesh)# no ethernet-vlan-transparent
   ```

4. Exit the configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-profile-mesh)# end
   ```

The mesh profile is configured, VLAN transparency is disabled to ensure VLAN awareness, and the device returns to privileged EXEC mode.

Associate the wireless mesh to an AP profile (CLI)

Associate Wireless Mesh to an AP Profile using commands.

Associate a wireless mesh to an AP profile to ensure proper configuration and management of AP.

Use these steps to associate the wireless mesh to an AP profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile and enter AP profile configuration mode using the **ap profile** *ap-profile-name* command.

Example

```
Device(config)# ap profile new-ap-join-profile
```

3. Configure the mesh profile in AP profile configuration mode using the **mesh-profile** *mesh-profile-name* command.

Example

```
Device(config-ap-profile)# mesh-profile Mesh_Profile
```

4. Configure the Secure Shell (SSH).

Example

```
Device(config-ap-profile)# ssh
```

5. Specify the AP management username and password for managing APs using the **mgmtuser username** *username* **password {0 | 8}** *password* command.

Example

```
Device(config-ap-profile)# mgmtuser username Cisco password 0 Cisco secret 0
 Cisco
```

- **0**: Specifies an UNENCRYPTED password.
- **8**: Specifies an AES encrypted password.

> **Note**
>
> While configuring a username, ensure that special characters are not used as they can lead to configuration errors.

6. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

The AP profile is configured with the wireless mesh, allowing for proper management and operation of the AP.

Attach site tag to an access point (CLI)

Attach site tag to an AP using commands.

Attach a site tag for AP identification and configuration management.

Use these steps to attach a site tag to an AP:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure APs and enters ap-tag configuration mode using the **ap** *mac-address* command.

   Example

   ```
   Device(config)# ap F866.F267.7DFB
   ```

3. Map a site tag to the AP using the**site-tag** *site-tag-name* command.

   Example

   ```
   Device(config-ap-tag)# site-tag new-flex-site
   ```

   Note

   Associating Site Tag causes the associated AP to reconnect.

4. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

The AP is now associated with the specified site tag and will reconnect.

Configure switch interface for APs (CLI)

Configure Switch Interface for APs using commands.

Configure a switch interface for APs using CLI to ensure proper VLAN assignment and trunk settings.

Use these steps to configure switch interface for APs:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the interface to be added to the VLAN.

   Example

   ```
   Device(config)# interface <int-id>
   ```

3. Assign the allowed VLAN ID to the port using the **switchport trunk native vlan** *vlan-id* command.

   Example

   ```
   Device(config-if)# switchport trunk native vlan 2660
   ```

4. Assign the allowed VLAN ID to the port using the **switchport trunk allowed vlan** *vlan-id* command.

   Example

   ```
   Device(config-if)# switchport trunk allowed vlan 2659,2660
   ```

5. Sets the trunking mode to trunk unconditionally.

   Example

   ```
   Device(config-if)# switchport mode trunk
   ```

   > **Note**
   >
   > When the controller works as a host for spanning tree, ensure that you configure portfast trunk, using **spanning-tree portfast trunk** command, in the uplink switch to ensure faster convergence.

6. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

The switch interface is successfully configured for AP connectivity, enabling effective VLAN management and ensuring faster network convergence for connected APs.

Flex resilient with flex and bridge mode AP configuration verification

Provides commands to verify Flex Resilient with Flex and Bridge Mode AP Configuration.

Use the verification commands to view details about AP mode and model, MAP mode details, RAP mode details, and the status of the Flex Profile–Resilient feature.

Use this command to view details about the AP mode and model.

```
Device# show ap name <ap-name> config general | inc AP Mode
AP Mode                                          : Flex+Bridge
AP Model                                         : AIR-CAP3702I-A-K9
```

Use this command to view the MAP mode details.

```
Device# show ap name MAP config general | inc AP Mode
AP Mode                                          : Flex+Bridge

```

SuiteB ciphers in FlexConnect mode

Details SuiteB-1X and SuiteB-192-1X security enhancements in FlexConnect, providing configuration procedures for SuiteB ciphers via GUI and CLI, support for advanced encryption algorithms, and verification steps for SuiteB cipher status.

A SuiteB cipher is a cryptographic suite used in FlexConnect mode that:

- enhances enterprise authentication key management by supporting SuiteB-192-1X (AKM 192-1X) and SuiteB-1X (AKM 11)
- operates within the constraints of Galois Counter Mode Protocol (GCMP-128 and GCMP-256) and Counter Cipher Mode with Block Chaining Message Authentication Code Protocol (CCMP-256) for secure key derivation, and
- is incorporated in Cisco WLAN FlexConnect mode from Cisco IOS XE 17.15.1, extending support already available in local mode.

Additional reference information

- WPA2 FlexConnect Mode:
  - SUITEB192-1X ciphers are CCMP-256 and GCMP-256.
  - SUITEB-1X ciphers are GCMP-128.
- WPA3 FlexConnect Mode:
  - SUITEB192-1X cipher is GCMP-256.
  - SUITEB-1X cipher is GCMP-128.

Wi-Fi 7 compliant AP constraints

Wi-Fi 7 WPA3 Security Constraints:

- Open authentication as Wi-Fi 7 is not permitted.

- WPA1 as Wi-Fi 7 is not permitted.
- WPA2 as Wi-Fi 7 is not permitted.
- WPA3 is permitted with restrictions:
  - SAE(24/25) is permitted with GCMP-256.
  - SAE(8/9) is permitted. (It is beaconed as a Wi-Fi 7 client. This is a deviation from the actual security constraint.)
  - WPA2 with PMF is permitted.
  - 802.1x-SHA256 with PMF is permitted.
  - Suite-B-192 with PMF is permitted.

Note

When you enable multi-ciphers (GCMP-128 + GCMP-256) and multi-AKMs (SuiteB + SuiteB-192) on a WLAN, clients that support WPA3 security may not support GCMP-128 encryption. If clients only support GCMP-128 encryption, they will not be able to join the combination of GCMP-128 + GCMP-256 ciphers with SuiteB and SuiteB-192 AKMs.

Configure SuiteB ciphers (GUI)

Follow these steps to configure SuiteB ciphers using the GUI.

Configure SuiteB ciphers for WLAN security using the system GUI to ensure compliance with SuiteB security standards.

Use these steps to configure SuiteB ciphers:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. In the **General** tab, enter the **Profile Name**, **SSID**, and the **WLAN ID**.
4. Choose **Security** > **Layer2**, select one of the following options:
   - **WPA + WPA2**
   - **WPA2 + WPA3**
   - **WPA3**

   The **Auth Key Mgmt (AKM)** section will be populated with the possible AKMs supported by the cipher that is selected in the **WPA2/WPA3 Encryption** section. Valid cipher and AKM combinations are displayed in the **Auth Key Mgmt (AKM)** section.
5. In the **WPA2 Encryption** section, select one of the following ciphers:
   - **CCMP256**
   - **GCMP128**
   - **GCMP256**

> **Note**
>
> The **AES(CCMP128)** cipher is selected by default. Multiple ciphers are not currently supported. Clear the **AES(CCMP128)** cipher check box and then select the desired cipher.

Valid cipher and AKM combinations are displayed in the **Auth Key Mgmt (AKM)** section.

6. In the **Fast Transition** section and in the **Status** drop-down list, select **Disabled**.

> **Note**
>
> Disable **Fast Transition** when Suite-B cipher (GCMP256/CCMP256/GCMP128) is configured.

7. In the **Auth Key Mgmt (AKM)** section, check the **SUITEB-1X** check box.
8. Click **Apply to Device**.

The SuiteB ciphers are configured and applied successfully to the selected WLAN profile.

Configure Suite-B ciphers (CLI)

Describes the CLI configuration steps to configure Suite-B ciphers.

Configure Suite-B ciphers for WLAN using CLI to enhance wireless security.

Use these steps to configure Suite-B ciphers:

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile and SSID using **wlan** *wlan-profile-name wlan-id ssid-name* command.

   Example

   ```
   Device(config)# wlan suiteb-profile 17 suiteb-ssid01
   ```

   Enters the WLAN configuration mode.

3. Configure the CCMP-128 support using **security wpa wpa2 ciphers** {**aes** | **ccmp256** | **gcmp128** | **gcmp256**} command.

Example

```
Device(config-wlan)# security wpa wpa2 ciphers aes
```

Suite-B ciphers are configured for the specified WLAN, enhancing the security protocols available for wireless connections.

Configure GCMP-128, GCMP-256, or CCMP-256 (CLI)

This task guides you through configuring WPA2 support with advanced ciphers on a WLAN profile to enhance wireless security.

Use these steps to configure WPA2 support with advanced ciphers on a WLAN profile.

Procedure

1. Configure the WPA2 support for a WLAN profile.

   Example

   ```
   Device(config-wlan)# security wpa wpa2
   ```

2. Disable security AKM for 802.1X.

   Example

   ```
   Device(config-wlan)# no security wpa akm dot1x
   ```

3. Disable the SuiteB CCMP-128 cipher.

   Example

   ```
   Device(config-wlan)# no security wpa wpa2 ciphers ccmp128
   ```

4. Configure either the CCMP-256 cipher, the GCMP-128 cipher, or the GCMP-256 cipher.

   Example

   ```
   Device(config-wlan)# security wpa wpa2 ciphers gcmp256
   ```

5. Set the authentication list for IEEE 802.1X.

   Example

   ```
   Device(config-wlan)# security dot1x authentication-list suiteb-authlist
   ```

The WLAN profile is configured with enhanced WPA2 support using advanced ciphers, improving the security of wireless communications on your network.

Verify SuiteB cipher status

Describes the verification of the suiteB cipher status with th commands.

Verify SuiteB cipher in a WLAN profile

To verify the SuiteB cipher status in a WLAN profile, use this command:

```
Device# show wlan id 3
saurabh-vwlc#show wlan id 3
WLAN Profile Name     : FIPS
================================================
Identifier                                      : 3
Network Name (SSID)                             : FIPS
Status                                          : Enabled
.
.
.
Security
    802.11 Authentication                       : Open System
    Static WEP Keys                             : Disabled
    802.1X                                      : Disabled
    Wi-Fi Protected Access (WPA/WPA2)           : Enabled
        WPA (SSN IE)                            : Disabled
        WPA2 (RSN IE)                           : Enabled
            AES Cipher                          : Enabled
            CCMP256 Cipher                      : Enabled
            GCMP128 Cipher                      : Disabled
            GCMP256 Cipher                      : Disabled
        Auth Key Management
            802.1x                              : Enabled
            PSK                                 : Disabled
            CCKM                                : Disabled
            FT dot1x                            : Disabled
            FT PSK                              : Disabled
            PMF dot1x                           : Disabled
            PMF PSK                             : Disabled
            SUITEB-1X                           : Disabled
            SUITEB192-1X                        : Enabled
.
.
.
```

Verify SuiteB cipher status using MAC address

To verify the SuiteB cipher status using a MAC address, use this command:

```
Device# show wireless client mac-address H.H.H detail
Client MAC Address : a8XX.ddXX.05XX
Client IPv4 Address : 169.254.175.214
…….
…….
Policy Type : WPA2
Encryption Cipher : CCMP256
Authentication Key Management : SUITEB192-1X
```

40 OEAP Link Test

Topics:

- OfficeExtend Access Point link test

OfficeExtend Access Point link test

Introduces OEAP Link Test fundamentals, and provides instructions for configuring the feature through CLI and GUI, including steps to check link test information and interpret results for effective troubleshooting.

An OfficeExtend Access Point Link (OEAP) Test is a diagnostic feature that

- helps determine the Datagram Transport Layer Security (DTLS) upload speed of the link between an OEAP and a controller
- assists in identifying network bottlenecks and reasons for functionality failures, and
- allows administrators to estimate link quality by running tests on demand.

Feature history for OfficeExtend Access Point link test

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 55: Feature history

Release	Feature	Feature information
Cisco IOS XE 17.5.1	OEAP Link Test	The Cisco OEAP Link Test feature allows you to determine the DTLS upload, link latency, and jitter of the link between an AP and the controller.

Feature scenarios

OEAP users may experience poor performance when connected to a teleworker AP. Running an OEAP link test can diagnose and address these issues.

- The test involves the AP sending synthetic packets to the controller. The controller returns them, and the AP measures link quality.

Use cases

You can use this feature to troubleshoot issues such as low throughput from the Cisco Catalyst 9800 Controller GUI. The OEAP link test provides crucial metrics like DTLS upload speed, link latency, and jitter, facilitating precise issue identification.

Configure OEAP link test (CLI)

Configure OEAP link test using commands.

Perform network diagnostics on an OEAP using CLI to troubleshoot network connectivity.

Procedure

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

2. Trigger network diagnostics on an OfficeExtend AP.

Example

```
Device# ap name ap18 network-diagnostic
```

The OEAP starts the network diagnostics process, allowing you to assess connectivity and performance.

Perform OEAP link test (GUI)

Perform a link test for the OEAP to ensure optimal connection quality and operational efficiency through the GUI.

Procedure

---

1. Choose **Monitoring > Wireless > AP Statistics**.

   In the list of APs, a **Link Test** icon is displayed in the **AP Name** column for OEAP-capable APs.

   > **Note**
   >
   > The **Link Test** icon is displayed only if an AP is OEAP capable and is configured to operate as OEAP.

2. Click **Link Test**.

   The controller runs the link test and displays the results.

The link test results are displayed after selecting the OEAP.

Verify OEAP link test

Verify OEAP Link Test.

To verify network diagnostics information, use this command:

```
Device# show FlexConnect office-extend diagnostics

Summary of OfficeExtend AP Link Latency

CAPWAP Latency Heartbeat

Current: current latency (ms)
Min: minimum latency (ms)
Max: maximum latency (ms)

Link Test

```

41 Cisco OEAP Split Tunneling

Topics:

- Cisco OEAP split tunneling

Cisco OEAP split tunneling

Introduces Cisco OEAP split tunneling, outlining traffic management concepts, prerequisites, restrictions, and use cases, and provides configuration workflows, detailed steps to create and apply IP and URL ACLs, policy profile setup, and verification of split tunnel operation.

Cisco OEAP split tunneling is a feature that

- provides secure communications from a controller to an AP at a remote location
- seamlessly extends the corporate WLAN over the internet to an employee's residence, and
- provides segmentation of home and corporate traffic using the split tunneling feature.

Routing all traffic through traditional VPNs increases volume, slows resource access, and negatively impacts remote user experience. Split tunneling allows for home device connectivity without security risks to corporate policy.

Feature history for Cisco OEAP split tunneling
Table 56: Feature history

Release	Feature	Feature information
Cisco IOS XE 17.8.1	IPv6 Support	IPv6 addressing is supported on the Cisco OEAP Split Tunneling feature.
Cisco IOS XE 17.7.1	Cisco OEAP split tunneling	The split tunneling feature in Cisco OfficeExtend Access Point (OEAP) provides a mechanism to classify client traffic, based on packet content, using access control lists (ACLs).

IPv6 address support for Cisco OEAP split tunneling

From Cisco IOS XE 17.8.1, IPv6 addressing is supported. You can disable IPv6 addressing only by disabling the feature.

The end-to-end network should support IPv6. Both the corporate network (controller, corporate gateway, and other related components) and the home network (wireless clients, home router, and others) should support IPv6.

Traffic to Software as a Service (SaaS) applications such as Cisco WebEx, Microsoft SharePoint, Microsoft Office365, Box, and Dropbox, which are required as part of the work routine, do not need to go through the corporate network when using the split tunneling feature.

Cisco OEAP split tunneling traffic management

Cisco OEAP split tunneling traffic management information.

A Cisco OEAP split tunnel is a network feature that

- classifies client traffic based on packet content using Access Control Lists (ACLs)
- switches matching packets locally from Cisco OEAP, and
- centrally switches other packets over Control and Provisioning of Wireless Access Points (CAPWAP).

Cisco OEAP provides seamless connectivity by broadcasting distinct Service Set Identifiers (SSIDs) for corporate use and personal use allowing for differentiated handling and prioritization of network traffic. Corporate SSID clients obtain their IP addresses from the central DHCP server within the corporate network. With split tunneling enabled, when a client connected to the corporate SSID attempts to access a device within a home network, the OEAP efficiently manages

network traffic by performing Network Address Translation (NAT) or Port Address Translation (PAT) between the client's internal network and the home network.

These examples explains Cisco OEAP split tunneling manages and differentiates network traffic for various use cases:

- VPN Split Tunnel Example: Corporate data can be sent through the secure corporate VPN while allowing personal data to be routed directly to the internet for enhanced performance.
- Home Network Example (SSID): Devices connected to the home SSID receive IP addresses either from the local AP DHCP server or directly from home network equipment when the firewall feature is switched off.

By segmenting traffic, OEAP split tunneling ensures optimized use of WAN bandwidth, improved network performance, and increased security by distinguishing between corporate and personal data streams.

Prerequisites for Cisco OEAP split tunneling

Cisco OEAP split tunneling prerequisites.

Hardware Requirements

Cisco Wave 2 APs or Cisco Catalyst 9100AX Series APs

Configuration Requirements

URL filter list that matches the ACL name configured in split tunneling

Restrictions for Cisco OEAP split tunneling

Cisco OEAP Split Tunneling restrictions.

These requirements outline the restrictions applicable to Cisco OEAP split tunneling:

- Cisco OfficeExtend Access Points (OEAPs) are not supported when Embedded Wireless Controller on Catalyst Access Points (EWC) is used as a controller.
- Mesh topology is not supported.
- Clients connected on a personal SSID or the home network (AP native VLAN) will not be able to discover devices.
- Split tunneling is not supported in standalone mode.
- URL split tunneling supports only up to 512 URLs.
- Specify actions, like deny or permit, only on the URL filter list, not for individual entries.
- If the URL-based ACL contains wildcard URLs, only ten URLs are supported.
- Use up to 128 IP address ACEs (rules) in the IP ACL for split tunneling.
- URL-based split tunnelling only works with IPv4 addresses.

DNS IP addresses restrictions

These requirements limit the amount of DNS IP addresses that can be snooped:

- An AP can snoop 4095 IP addresses per DNS response, if IP addresses are less than 150,000.
- An AP can snoop 10 IP addresses per DNS response, if IP addresses are between 150,000 and 200,000.
- An AP can snoop 5 IP addresses per DNS response, if IP addresses are between 200,000 and 250,000.
- An AP can snoop one IP address per DNS response, if IP addresses are greater than 250,000.

IPv6 Addressing restrictions

These restrictions apply to IPv6 addressing for Cisco OEAP split tunneling:

- Multihoming, which involves multiple router advertisement prefixes, is not supported. If a home network receives multiple prefixes, the AP connected to the controller uses one prefix.
- The system does not support roaming.
- Filtering is not supported on the upstream traffic towards the wireless client.
- Split tunneling is disabled for clients with duplicate IPv6 addresses. Traffic for these clients is forwarded centrally to the controller.
- DHCPv6 prefix delegation is not supported for wireless clients.
- If the corporate prefix length is smaller than the home prefix length, split tunneling for a particular client is disabled.

Use cases for Cisco OEAP split tunneling

Cisco OEAP Split Tunneling Use Cases.

Before Cisco IOS XE 17.7.1, you could use IP ACLs for split tunneling. Cloud services, such as Cisco Webex, could be accessed directly. These services bypassed the corporate network. As a network administrator, you maintained the list of IP addresses that Cisco Webex used.

Starting with Cisco IOS XE 17.7.1, when you use the Cisco OEAP Split Tunneling feature, provide only the DNS names that Cisco Webex uses. The AP then routes traffic from these DNS names directly to the internet instead of through the corporate network.

How Cisco OEAP split tunneling works

Configure Cisco OEAP split tunneling.

Summary

This process involves configuring Cisco OEAP split tunneling by performing multiple steps that include creating ACLs, adding them to profiles, enabling split tunnelling, and verifying the configuration.

Workflow

The process involves these stages:

1. Defining ACLs: Create IP address ACL or URL ACL to specify allowed network paths.
2. Profile association: The administrator adds these ACLs to the FlexConnect Profile to prepare for policy enforcement.
3. Policy activation: Enable split tunneling on the policy profile to segment and direct data flows.
4. Configuration confirmation: The administrator verifies successful configuration to ensure policy compliance, and network functionality.

Result

You have configured Cisco OEAP Split Tunneling, allowing effective management of network traffic and enhanced security for remote devices.

Create an IP address ACL (CLI)

Create an IP Address ACL using commands.

You can configure an IP address-based ACL on network devices to control and secure traffic flow.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Define an extended IPv4 access list using a name.

Example

```
Device(config)# ip access-list extended vlan_oeap
```

> **Note**
>
> An IP ACL can define a default action if no matches exist in the URL ACL.

3. Deny IP traffic from any host.

Example

```
Device(config-ext-nacl)# 10 deny ip any 10.10.0.0 0.0.255.255
```

4. Permit IP traffic from any destination host.

Example

```
Device(config-ext-nacl)# 20 permit ip any any
```

5. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ext-nacl)# end
```

The IP address ACL effectively filters traffic according to the specified rules on the network device.

Create a URL ACL (CLI)

Create a URL ACL using commands.

Create a URL Access Control List (ACL) on a network device using CLI, enabling control over which URLs can be accessed based on security policies.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the URL filter list.

   Example

   ```
   Device(config)# urlfilter list vlan_oeap
   ```

   Your list name must not exceed 32 alphanumeric characters.

3. Configure the action: Permit (traffic is allowed directly on the home network) or Deny (traffic is directed to the corporate network).

   Example

   ```
   Device(config-urlfilter-params)# action permit
   ```

4. Configure the URL list as post authentication filter.

   Example

   ```
   Device(config-urlfilter-params)# filter-type post-authentication
   ```

5. Configure a URL.

   Example

   ```
   Device(config-urlfilter-params)# url wiki.cisco.com
   ```

6. Optional: Configure a URL.

   Example

   ```
   Device(config-urlfilter-params)# url example.com
   ```

   Use this option when you want to add multiple URLs.

7. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-urlfilter-params)# end
   ```

You have configured the URL ACL successfully, allowing specific URLs to be permitted or denied access through the network device according to the parameters set during configuration.

Add an ACL to a FlexConnect profile (GUI)

Associate an Access Control List (ACL) with a FlexConnect profile, applying filtering and control policies to FlexConnect APs.

Use this procedure to apply an ACL and URL filtering to a FlexConnect profile, enabling traffic control and optional OfficeExtend mode for remote APs.

Before you begin

Use these steps to add an ACL to a FlexConnect profile:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the target FlexConnect profile.

   Example

   ```
   Device(config)# wireless profile flex default-flex-profile
   ```

3. Define the ACL policy to associate with the profile.

   Example

   ```
   Device(config-wireless-flex-profile)# acl-policy vlan_oeap
   ```

4. Configure a URL filter list, if required.

   Example

   ```
   Device(config-wireless-flex-profile-acl)# urlfilter list vlan_oeap
   ```

5. Exit ACL configuration mode to return to the FlexConnect profile.

   Example

   ```
   Device(config-wireless-flex-profile-acl)# exit
   ```

6. Enable OfficeExtend mode for the FlexConnect AP, if applicable.

   Example

   ```
   Device(config-wireless-flex-profile)# office-extend
   ```

7. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

The ACL and associated URL filter are applied to the selected FlexConnect profile, with OfficeExtend mode enabled if configured. The changes take effect for FlexConnect APs using this profile.

Enable split tunneling in a policy profile

Enable Split Tunnelling in a Policy Profile using commands.

Enable split tunneling in a policy profile to optimize network traffic and enhance performance by allowing specified traffic to bypass the central network and directly access the internet.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a FlexConnect profile.

   Example

   ```
   Device(config)# wireless profile flex default-flex-profile
   ```

3. Disable central association and enable local association for locally switched clients.

   Example

   ```
   Device(config-wireless-flex-profile)# no central association
   ```

4. Configure a split MAC ACL name.

   Example

   ```
   Device(config-wireless-flex-profile)# flex split-mac-acl vlan_oeap
   ```

   Note

   Ensure that you use the same *acl-policy-name* in the FlexConnect profile.

5. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config-wireless-flex-profile)# end
   ```

Enable split tunneling in the policy profile so that traffic defined in the ACL can locally switch, which improves bandwidth use and network performance.

Verify the Cisco OEAP split tunnel configuration

Verify the Cisco OEAP split tunnel configuration.

To verify the split tunneling DNS ACLs per wireless client on the AP side, use this command:

```
Device# show split-tunnel client 00:11:22:33:44:55 access-list

Split tunnel ACLs for Client: 00:11:22:33:44:55

IP ACL: SplitTunnelACL

Tunnel packets Tunnel bytes NAT packets NAT bytes
             1          242           3       768

URL ACL: SplitTunnelACL

Tunnel packets Tunnel bytes NAT packets NAT bytes
             3          778           0         0

Resolved IPs for Client: 00:11:22:33:44:55 for Split tunnel

HIT-COUNT       URL             ACTION  IP-LIST

1               base1.com       deny.   203.0.113.0
                                        203.0.113.1

2               base2.com       deny.   203.0.113.2

3               base3.com       deny.   203.0.113.5
```

To verify the current binding between a WLAN and an ACL, use this command:

```
Device# show split-tunnel mapping

VAP-Id       ACL Name
    0        SplitTunnelACL
```

To verify the content of the current URL ACL, use this command:

```
Device# show flexconnect url-acl

ACL-NAME          ACTION      URL-LIST

SplitTunnelACL    deny        base.com
```

42 Access Points Survey Mode

Topics:

- AP survey modes

AP survey modes

Outlines AP survey modes, describing their purpose for RF parameter configuration and site surveys, provides login and SSID access details, recommends browser usage, and guides you through enabling survey mode on supported Cisco Catalyst APs.

An AP survey mode is a specialized operational state that

- enables the AP GUI for configuring RF parameters
- facilitates site survey investigation at customer sites, and
- is introduced for Cisco Catalyst 9136 Series APs and other upcoming AP models.

Additional reference information

- Accessing the GUI: Enter 'admin' as the default login and 'admin' as the default password to access AP survey mode from the GUI. Both usernames and passwords are case sensitive.
- SSID broadcast and connection: When the AP is in survey mode, it broadcasts an SSID by default. The default password to connect to this SSID is 'password' (case sensitive).
- Recommended browser: Use Google Chrome to access the AP GUI in survey mode.

Enable survey mode

Enable survey mode on an AP by running the **ap-type site-survey** command from the AP CLI.

Restrictions for access points survey mode

- When survey mode is active, certain GUI features such as WAN, Firewall, and Network Diagnostics are hidden.
- To restore visibility of hidden features on the AP GUI, switch the AP to CAPWAP mode by running the **ap-type capwap** command from the AP CLI. In CAPWAP mode, the AP GUI becomes accessible when the **OfficeExtend AP** field is enabled in the FlexConnect profile page linked to that AP.

43 AP Deployment Mode

Topics:

- AP deployment mode

AP deployment mode

Introduces AP deployment mode concepts, detailing relevant use cases, provides procedures for configuring deployment modes via both GUI and CLI, guides users in viewing deployment status, and explains verification steps to ensure proper AP operation.

An AP deployment mode is a configuration feature that

- enables Cisco Catalyst 9124AX Series Outdoor AP to operate in indoor mode within the -E regulatory domain
- expands available channels to include U-NII-1 and U-NII-2 in addition to U-NII-2C channels, and
- applies specifically to the -E regulatory domain for increased channel availability.

Supporting reference information

- For more information on the regulatory domain, see Countries and Regulations.

  For more information on U-NII-1 and U-NII-2, see https://en.wikipedia.org/wiki/Unlicensed_National_Information_Infrastructure.

Restrictions for AP deployment mode

AP deployment mode use case.

- This feature applies to Cisco Catalyst 9124AX Series Outdoor APs only.
- We recommend operating Cisco Catalyst 9124AX Series Outdoor APs in Indoor mode in environments such as greenhouses or walk-in freezers to ensure optimal network performance and equipment longevity.

Configure an AP deployment mode (GUI)

Configure AP deployment mode using the GUI.

Configure the deployment mode of an AP to fit the intended environment using GUI.

Use these steps to configure the AP deployment mode:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.

   To add a new AP join profile, see *Configuring an AP Profile (GUI)*. To modify an existing AP join profile, select the required AP join profile.

2. Click **General** tab.
3. From the **Deployment mode** drop-down list, select one of these options:
   - *Default or Outdoor*: Select this option if you want to configure the AP in outdoor mode. By default, Cisco Catalyst 9124AX Series APs are configured in outdoor mode.
   - *Indoor*: Select this option if you want to configure the AP in indoor mode for enclosed spaces like greenhouses or walk-in freezers.

> **Note**
>
> When the deployment mode is changed, the system prompts you to confirm the change. Select **Yes** to accept the change.

4. Click **Apply to Device**.

The AP deployment mode is successfully configured to match its environment, ensuring optimal performance.

View deployment status

View deployment status using GUI.

View the deployment status after configuring the AP deployment mode.

Before you begin

Use these steps to view deployment status:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **All Access Points** tab, click on a Cisco Catalyst 9124AX Series Access Point access point.
3. In the **Edit AP** window, select the **Advanced** tab to view the default and current mode of the AP.

The deployment status is displayed.

Configure AP deployment mode (CLI)

Configure AP deployment mode using commands.

Configure the deployment mode for an AP using CLI commands to ensure it operates effectively in the desired mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile1
   ```

3. Configure the outdoor AP to operate in indoor mode.

Example

```
Device(config-ap-profile)# dual-mode-ap-deployment-mode indoor
```

4. Exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

The AP is successfully set to the specified indoor mode, ensuring that it operates under the correct deployment configuration.

Verify AP deployment mode

Verify AP deployment mode.

To verify whether the AP indoor mode is enabled or not, use this command:

```
Device# show ap name APXXXX.31XX.83XX config general
Cisco AP Name   : APXXXX.31XX.83XX
================================================

Cisco AP Identifier                              : 4ca6.4d22.f140
Country Code                                     : Multiple Countries : CZ,US
Regulatory Domain Allowed by Country             : 802.11bg:-AE   802.11a:-ABE
   802.11 6GHz:-BE
Radio Authority IDs                              : None
AP Country Code                                  : CZ  - Czech Republic
AP Regulatory Domain
  802.11bg                                       : -E
  802.11a                                        : -E
.
.
.AP Indoor Mode                                  : Enabled
```

To verify the available channel list in AP console, use this command:

```
AP# show rrm receive configuration
RRM configuration slot 1
==================================
Group Id
Switch Id            :0904640500ff
Group Cnt            :57454
IP address           :9.4.100.5
Encrypted            :0
Version              :1
Key                  :ff3fff55ffffff42ffff2cff6d0affff
Domain               :default
Key Name             :Channel Count        :19
TX Chans             :36 40 44 48 52 56 60 64 100 104 108 112 116 120 124 128
 132 136 140
```

To view the indoor deployment details in AP console, use this command:

```
AP# show capwap client configuration
AdminState                         : ADMIN_ENABLED(1)
```

```
Name                                 : AP3C57.31C5.9478
Location                             : default location
Primary controller name              : Rack10_katar
Primary controller IP                : 9.4.100.5
Secondary controller name            :
Tertiary controller name             :
.
.
.Indoor Deployment                  : 2!Indoor Deployment: 2 signifies that the
 AP is in Indoor mode.
!Indoor Deployment: 0 signifies that the AP is in Outdoor mode.
```

44 Access Point Location

Topics:

- AP auto location support

AP auto location support

Introduces AP Auto Location Support, covering advanced features in Cisco IOS XE 17.12.1, ultra wide band ranging, GNSS raw data streaming via gRPC, configuration of geolocation and ranging (GUI and CLI), fine time measurement, air pressure reporting, and verification of AP location settings.

Access points auto location support is a wireless network feature that

- automates the identification and assignment of geographic locations to APs
- uses technologies such as the Global Positioning System (GPS) or a Global Navigation Satellite System (GNSS), and
- enhances the accuracy and efficiency of wireless network management.

Feature history for AP auto location support
Table 57: Feature history

Release	Feature information
Cisco IOS XE 17.12.1	The Access Point Auto Location Support feature helps to effectively self-locate APs in a global coordinate by combining various ranging technologies and algorithms.
Cisco IOS XE 17.13.1	The improved Access Point Auto Location Support feature helps wireless clients to leverage Fine Timing Measurement (FTM) and AP GNSS for indoor navigation.
Cisco IOS XE 17.15.2	Ultra Wide Band (UWB) technology uses various methods to determine the position and distance between APs. UWB is supported in the Cisco Wireless 9178I Series Wi-Fi 7 APs, Cisco Wireless 9176I Series Wi-Fi 7 APs, and Cisco Wireless 9176D1 Series Wi-Fi 7 APs to perform AP to AP ranging.

The AP auto location solution mitigates common challenges in enterprise environments where manual AP location entry is often inaccurate or neglected. This system

- automates AP location detection using GNSS and Fine Timing Measurement (FTM) technologies, when accessible
- uses manual anchors to support location determination when GNSS signals are unavailable, and
- requires adequate AP density to ensure inter-AP communication at maximum power for precise geolocation.

Process Overview

Auto location support enhances efficient, precise AP management in settings where traditional GNSS solutions are impractical.

- Segmentation and Labeling: Dividing a large number of APs into smaller, floor-specific segments to determine geolocations.
- Ranging and Geolocation: Leveraging strong GNSS signals to assist APs with weak signals, through inter-AP ranging data and FTM technology.
- Fallback with Manual Anchors: Implementing manual anchors as needed to maintain location accuracy in areas without GNSS reception.

Use Case

Supported Access Points

Auto location support is effectively applied for self-locating APs within a building or a specific floor, aiding seamless network integration and management.

For information about APs that support this feature see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html.

Advanced functionalities in Cisco IOS XE 17.12.1

Advanced functionalities in Cisco IOS XE 17.12.1

- Client FTM: It enhances indoor navigation by allowing AP range checks from unassociated clients through designated WLANs on 5-GHz and 6-GHz bands.
- Air Pressure Reporting and Updates: APs send air pressure data to the controller, with RPC and Privileged EXEC mode commands to enable collection. Samples are collected at regular intervals, such as every 30 seconds for 10 minutes.
- Band Filters: Optimizes AP-to-AP ranging by enhancing site-tag efficiency on specified bands like 5 GHz or 6 GHz.
- Ranging Completion Notification: The controller oversees APs for ranging completion, relaying status to Cisco Spaces upon completion.
- AP Movement Alarm: When an AP is disconnected and then reconnected at a new location, the system reports an alarm to the controller, which updates the system with syslog entries and alerts Cisco Spaces.

Ultra-wideband ranging

Ultra-wideband ranging infromation.

Ultra-wide band ranging is a technology-based method that

- determines position and distance between APs using a range of techniques
- employs double-sided two-way ranging between UWB-capable APs and UWB-enabled devices to enhance accuracy, and
- differentiates multipath components through short pulse duration and wide bandwidth.

UWB for increased accuracy

UWB technology, combined with precise time measurement, enhances accuracy in environments with heavy multipath conditions, including concrete structures or metallic surfaces. This technology optimizes performance and reliability by reducing signal reflection and interference, thereby enhancing the precision of AP AnyLocate in specific Cisco Wireless AP series.

In particular, UWB radios in Cisco Wireless 9178I Series Wi-Fi 7 APs, 9176I Series Wi-Fi 7 APs, and 9176D1 Series Wi-Fi 7 APs are utilized to conduct AP-to-AP ranging. When combined with Wi-Fi-based ranging, UWB yields superior results in specific environments.

Group ranging

Group ranging is a technique where ranging is exclusively conducted within a group of identified APs.

- These APs can span different site tags.
- A list of AP radio MAC addresses must be provided as input to execute group ranging.

Group ranging does not have CLI support and relies on Network Configuration Protocol (NETCONF) and Remote Procedure Calls (RPC) for implementation.

Global Navigation Satellite System raw data streaming through gRPC

GNSS raw Ddata streaming through gRPC info.

Global Navigation Satellite System (GNSS) data streaming is a feature that

- streams high-volume raw GNSS data from APs directly to Cisco Spaces
- uses the Google Remote Procedure Call (gRPC) protocol for efficient data handling, and
- reduces the load on network controllers.

Supported equipment and features

- Internal GNSS antennas
- External GNSS data through Gypsum USB dongle
- Cisco Catalyst 9120 Series AP, Cisco Catalyst 9130 Series AP, Cisco Catalyst 9136 Series AP, Cisco Catalyst 9162 Series AP, Cisco Catalyst 9164 Series AP, Cisco Catalyst 9166 Series AP, Cisco Catalyst 9166D Series AP, Cisco Wireless 9178 Series AP, and Cisco Wireless 9176 Series AP.

Configuration Information

- There is no configuration on the controller.
- The AP sends GNSS data to Cisco Spaces through gRPC once the connection is established.

GNSS raw data streaming through gRPC

Summary

This process describes how GNSS data is transmitted from APs to Cisco Spaces using gRPC technology.

Workflow

1. The APs receive GNSS data either internally or through the Gypsum module.
2. After the controller is added to the Cisco Spaces connector, the AP establishes a gRPC tunnel to the Cisco Spaces connector.
3. Cisco Spaces pushes the configuration to set the GNSS reporting interval on the AP.
4. The AP sends GNSS data to Cisco Spaces at the configured interval.

Result

The process successfully transfers GNSS data from the APs to Cisco Spaces, ensuring seamless communication.

Restrictions for GNSS raw data streaming through gRPC

- AP Join Profile Preparation: You must create the AP join profile before adding the controller to the Cisco Spaces connector.
- Interval Reset Upon Reload: If the AP reloads, note that the interval duration resets. The AP must then wait for 24 hours for the connector to push the configuration again.
- Data Sending Restriction: Ensure that GNSS raw data streaming cannot be explicitly disabled.

AP commands

Outline the available AP commands executable via the controller for effective network management.

These are the AP commands. These commands can be run from the controller using the **remote** command.

- **show spaces endpoint key access**
- **show spaces endpoint key authentication**
- **show spaces endpoint connection detail**
- **debug spaces <info/debug/error/warning/critical>**

Configure AP geolocation derivation using ranging (GUI)

Configure access point geolocation derivation using ranging GUI.

This task explains how to enable geolocation derivation for access points using ranging to determine their location.

Use these steps to configure access point geolocation derivation using ranging:

Procedure

1. Choose **Configuration** > **Wireless** > **Wireless Global**.
2. In the **AP Geolocation** section, click the **Geolocation Derivation Using Ranging** toggle button to enable geolocation derivation.

   Enabling **Geolocation Derivation Using Ranging** allows the AP to participate in location services using ranging for geolocation.
3. Click **Apply**.

> **Note**
>
> Once enabled, **Geolocation Derivation Using Ranging** updates the AP ranging capability on Cisco Spaces within approximately 30 minutes.

The AP is configured for geolocation derivation and is ready for use in location services employing ranging techniques.

Configure AP geolocation derivation using ranging (CLI)

Configure access point geolocation derivation using ranging using commands.

This task allows you to configure geolocation derivation for an access point using ranging, which can improve location accuracy.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable geolocation derivation using ranging.

Example

```
Device(config)# ap geolocation derivation ranging
```

> **Note**
>
> Use the **no** command to disable the feature.

Geolocation derivation is enabled for AP, which potentially improves its location estimation capabilities. If the configuration fails, verify the commands and check the device logs for errors.

Configure the AP Ranging Parameters through the GUI

Configure AP Ranging Parameters using the graphical user interface (GUI).

This task guides you through configuring the ranging parameters on an access point using the controller's graphical user interface.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add**.
3. In the **General** tab, enter the name and description of the corresponding AP join profile.
4. Click the **Geolocation** tab.
5. In the **Fine Time Management (FTM)** section, complete these steps:
   - Click the **FTM** toggle button to allow APs to use FTM for inter AP ranging.
   - In the **FTM Initiator Burst Size** field, specify the burst size value. The burst size determines the size of the transmitted frames. The valid range is between two and 31 frames. The default value is 16 frames per burst.
   - From the **FTM Initiator Burst Duration** drop-down list, choose a value. The burst duration determines the interval of the transmitted frames. The default value is 32 microseconds.
6. Click **Apply to Device**.

Upon completion, the access point will be configured with the specified ranging parameters, enhancing wireless communication by allowing accurate distance measurements.

Configure AP ranging parameters (CLI)

Set up AP geolocation ranging parameters to enable Fine Timing Measurement (FTM) for precise location tracking.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile1
   ```

3. Enable geolocation Fine Timing Measurement (FTM).

   Example

   ```
   Device(config-ap-profile)# geolocation ftm
   ```

4. Configure the geolocation FTM burst size.

   Example

   ```
   Device(config-ap-profile)# geolocation ftm initiator burst-size 8
   ```

   The burst size values are 4, 8, 16, 32 and 64 frames. The default value is 8 frames per burst.

5. Configure the geolocation FTM burst duration.

   Example

   ```
   Device(config-ap-profile)# geolocation ftm initiator burst-duration 32ms
   ```

   The default value is 32 microseconds.

The AP is configured with the specified geolocation ranging parameters for FTM.

Configure AP location (CLI)

Configure AP Coordinates and Floor Information using commands.

Accurately configure AP with their physical location and floor information for precise network management and location-based services.

Use these steps to configure the AP coordinates and the corresponding floor information.

> **Note**
>
> There are no corresponding GUI steps for this configuration.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Configure the longitude and latitude of the AP.

   Example

   ```
   Device# ap name cisco-ap1 geolocation coordinates 90 45
   ```

   The value range for longitude is from -180 to 180 degrees. The value range for latitude is from -90 to 90 degrees.

3. Configure the floor ID for the AP.

   Example

   ```
   Device# ap name cisco-ap1 floor 2147483647
   ```

   The floor ID range is from -2147483648 to 2147483647.

The AP has updated geographical coordinates and floor information, allowing accurate mapping and integration with location-based services.

Configure on-demand AP ranging (CLI)

Configure on-demand access point ranging using commands.

Improve the geolocation accuracy of APs through on-demand ranging configuration.

Use these steps to configure on-demand AP ranging:"

> **Note**
>
> There are no corresponding GUI steps for this configuration.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Enable accurate ranging using the 5 GHz or 6 GHz bands on APs under the configured site tag.

   Example

   ```
   Device# ap geolocation ranging site <cite>ap-site-tag</cite> accurate 5ghz
   ```

   > **Note**
   >
   > Client connections may be disrupted.

3. Enable accurate ranging using the 5 GHz or 6 GHz bands on all APs.

   Example

   ```
   Device# ap geolocation ranging all accurate 5ghz
   ```

   > **Caution**
   >
   > Client connections may be disrupted.

APs are configured for enhanced geolocation accuracy through on-demand ranging.

Enable fine time measurement (802.11mc) responder (GUI)

Enable fine time measurement (802.11mc) responder using GUI.

Enable the AP to respond to fine time measurement queries for indoor location determination.

Follow these steps to configure the AP to respond to fine time measurement queries:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.

   The **Add WLAN** window is displayed.
3. In the **General** tab, enter the **Profile Name**, the **SSID**, and the **WLAN ID**.
4. In the **Advanced** tab, under the **Geolocation** section, click the **Fine Time Measurement (FTM) Responder** toggle button to enable the AP to respond to time measurement queries sent from a client.

   The client sends time measurement queries to measure its distance to the AP and determine their indoor location.

   The **Advertise AP Location** field is displayed.
5. Click the **Advertise AP Location** toggle button to enable the AP to advertise its geolocation coordinates.
6. Click **Apply to Device** to save the configuration.

The AP is configured to respond to fine time measurement queries.

Configure fine time measurement (802.11mc) responder

Configure fine time measurement (802.11mc) responder using commands.

Configure a fine time measurement (802.11mc) responder to ensure it communicates accurate location information.

Follow these steps to configure a fine time measurement responder:

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Specify the WLAN name and ID.

   Example

   ```
   Device(config)# wlan wlan-profile 36 ssid1
   ```

   - *profile-name* is the WLAN name. Valid WLAN names can contain up to 32 alphanumeric characters
   - *wlan-id* is the wireless LAN identifier. The valid range is from 1 to 4096.
   - *ssid-name* is the SSID which can contain 32 alphanumeric characters.
3. Configure the FTM responder.

   Example

   ```
   Device(config-wlan)# geolocation ftm-responder
   ```
4. Configure the advertisement of AP location to clients.

Example

```
Device(config-wlan)# geolocation ftm-responder advertise-ap-location
```

5. Optional: Clear the AP geolocation best known FTM report.

Example

```
Device# clear ap geolocation ranging
```

The fine time measurement responder is configured successfully, allowing communication of accurate location information to compatible devices.

Configure air pressure reporting (CLI)

Configure air pressure reporting using commands.

This task allows the configuration of air pressure data reporting to optimize environmental monitoring.

Procedure

---

1. Enable privileged EXEC mode.

Example

```
Device> enable
```

Enter your password if you are prompted.

2. Configure sensor air pressure data collection either for all APs or specifically for APs within a site tag.

Example

```
Device# ap sensor air-pressure site sitetag1 duration 10
```

The value range of the duration of the air pressure reporting is from 1 minute to 1,440 minutes. The default is 10 minutes.

From Cisco IOS XE 17.15.1, the default air pressure sample interval is changed from 30 seconds to 60 seconds. For example, if the duration is set to 10 minutes, the APs send 10 samples, spaced at 60-second intervals each.

Air pressure data collection is configured for the specified access points, allowing for effective environmental monitoring and reporting.

Configure AP ultra wide band parameters (GUI)

Configure access point ultra wide band parameters using GUI.

Configure the ultra wide band parameters on an access point using the GUI.

Follow these steps to configure the UWB parameters:

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add**.
3. In the **General** tab, enter the name and description of the corresponding AP join profile.
4. Click the **Geolocation** tab.
5. In the **Ultra Wide Band (UWB)** section, complete these steps:
   - Click the **UWB** toggle button to allow APs to use UWB for inter AP ranging.
   - In the **UWB Burst Size** field, specify the burst size value. The size of the transmitted frames is determined by the burst size. The range is from 10 ro 100 frames. The default value is 32 frames per burst.
   - From the **UWB Burst Duration** drop-down list, choose a value. The interval of the transmitted frames is determined by the burst duration. The valid range is from 5 to 30 seconds. The default value is 10 seconds.
   - Click **Apply to Device**.

The AP is configured with the specified UWB parameters, allowing for optimized inter AP ranging and communication.

Configure access point ultra wide band parameters (CLI)

Configure access point ultra wide band ranging parameters using commands.

This task guides you through configuring ultra wide band (UWB) parameters for an AP, optimizing geolocation accuracy and efficiency.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile default-ap-profile
   ```

3. Enable default.

   Example

   ```
   Device(config-ap-profile)# geolocation uwb
   ```

4. Configure the geolocation UWB burst size.

   Example

   ```
   Device(config-ap-profile)# geolocation uwb initiator burst-size 32
   ```

   The range of burst size values is from 10 to 100 frames. The default value is 32 frames per burst.

Important

We recommend that you do not alter the burst size and the burst duration.

5. Configure the geolocation UWB burst duration.

Example

```
Device(config-ap-profile)# geolocation uwb initiator burst-duration 10s
```

The range of burst duration values is from 5 to 30 seconds. The default value is 10 seconds.

The AP has optimized UWB parameters, which enhance its geolocation functionality for improved accuracy.

Verify AP geolocation information

Verify AP geolocation information.

Verify AP geolocation ranging report

To verify the AP geolocation ranging report, run this command:

```
Device# show ap geolocation ranging report
RequestID     AP Name                          NeighborAP(Name/MAC)
     Type    Method  Dist(cm)  Channel   Band      Width(MHz)  AOA(elev)

```

> **Note**
>
> AoA which refers to the angle of arrival (azimuth and elevation) is included in the show command output from the Cisco IOS XE 17.15.2 release.

To view an AP geolocation ranging request, run this command:

```
Device# show ap geolocation ranging request
Request ID    SiteTag/Group/All APs             Mode          Method
Band      Requests  Responses  Reports    Start Time                End Time

------------------------------------------------------------------------------------------------
1             ALL APs                           Accurate      ALL
All       4         0          0          05/15/2024 14:33:33 UTC
```

> **Note**
>
> The method column is introduced from Cisco IOS XE 17.15.2 release.

To view the AP geolocation summary, run this command:

```
Device# show ap geolocation summary
AP Name                Radio MAC          Location  Location Longitude
Latitude    Major-axis Minor-axis Orientation Height Height   Height
Height
                                          Type      Source   (degrees)
(degrees)   (meters)   (meters)   (degrees)   Type   (meters) Uncertainty
Source

                                                             (meters)

------------------------------------------------------------------------------------------------
APCC9C.3EF1.0F30      10f9.20fd.f640     Ellipse   Manual   90.000000
90.000000    0          0          0.000000    NA     NA       NA
NA
```

To view the AP geolocation statistics, run this command:

```
Device# show ap geolocation statistics
Num APs with GNSS                  : 1
Num APs with manual height         : 0
Num APs with derived geolocation   : 0
Last geolocation derivation run    : 07/21/2023 08:54:21
```

To view the AP geolocation GNSS-capable summary, run this command:

```
Device# show ap geolocation gnss-capable summary
------------------------------------------------------------------------------------------------
AP Name                      Radio MAC          GPS Coverage    Antenna Type
 Last GPS fix
------------------------------------------------------------------------------------------------
```

```
APCC9C.3EF4.CF00             10f9.20fd.b6e0     No              Internal
 NA
```

Note

APs do not store the GNSS location. The location is recalculated after a reboot unless it is configured manually.

To view the AP geolocation ranging status, run this commands:

```
Device# show ap geolocation ranging status
```

```
Device# show ap name geolocation ranging status
```

To view the ranging capability of APs, run this command:

```
Device# show ap geolocation ranging capability
AP Name               FTM Responder   FTM Initiator
-----------------------------------------------------------------
AP0001.Cisco.CF00      Yes             Yes
AP0002.Cisco.0F30      Yes             Yes
AP-2800                No              No
AP0003.Cisco.82a0      No              No
```

45 SS IOT: Implement Wi-Fi Coexistence with ESL

Topics:

- Wi-Fi-IoT radio coexistence

Wi-Fi-IoT radio coexistence

Introduces Wi-Fi-IoT radio coexistence mechanisms, detailing collaborative and non-collaborative interference mitigation approaches, explaining PTA coordination for airtime sharing, and outlining performance improvements in environments with dense IoT devices.

Wi-Fi-IoT radio coexistence is a collaborative interference-reduction mechanism that

- minimizes signal interference between Wi-Fi and IoT radios operating on the 2.4 GHz ISM band
- utilizes Packet Traffic Arbitration (PTA) to coordinate airtime sharing between collocated radios, and
- improves the performance and reliability of wireless networks in environments with high IoT device density.

Packet Traffic Arbitration (PTA)

Packet Traffic Arbitration (PTA) is a coordination entity that provides per-packet authorization for transmissions. It dynamically manages the wireless medium based on traffic load, ensuring that high priority packets from either radio are granted access while preventing simultaneous transmissions that would cause collisions.

Collaborative and Non-collaborative Mechanisms

- Non-collaborative: Radios do not exchange information.
- Collaborative: Radios exchange real-time state information to negotiate medium access.

Difference between collaborative and non-collaborative mode

In non-collaborative mode, the IoT radio and the Wi-Fi radio each transmit whenever they have data, regardless of whether the other radio is currently in use. As a result, if a collision occurs when the Wi-Fi radio is busy because it is being used by the Wi-Fi chipset, the IoT radio cannot send its packet. In collaborative mode, the IoT radio asks the Wi-Fi radio for permission to transmit. Once permission is granted, the IoT radio transmits over the radio.

Feature history for Wi-Fi-IoT radio coexistence

This section explains the feature history details of the Wi-Fi-IoT radio coexistence feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 58: Feature history for Wi-Fi-IoT radio coexistence

Feature Name	Release Information	Feature Description
Wi-Fi-IoT radio coexistence	Cisco IOS XE 26.1.1	Wi-Fi-IoT radio coexistence is a collaborative interference-reduction mechanism that minimizes signal interference between Wi-Fi and IoT radios operating on the 2.4 GHz ISM band. It utilizes Packet Traffic Arbitration (PTA) to coordinate airtime sharing between collocated radios, improving the performance and reliability of wireless networks in environments with high IoT device density.

Best practices for Wi-Fi-IoT coexistence

This section explains the best practices for Wi-Fi-IoT coexistence.

- IOx application dependency: For Electronic Shelf Labeling (ESL) use cases, the coexistence feature requires an active IOx application. The IOx application must be installed and running on the AP to manage the IoT radio firmware.
- Use supported 6E platforms: During initial deployment, use the Cisco Catalyst 9162, 9164, or 9166 series APs.
- Controller priority: The controller's configuration commands take precedence over requests from local IOx applications.

How Wi-Fi-IoT coexistence works with IOx applications

This section explains how Wi-Fi-IoT coexistence works with IOx applications.

Wi-Fi-IoT coexistence enables the controller, the AP, and collocated third-party applications to manage radio airtime by facilitating a synchronized communication flow. The key components involved in the process are:

- The controller defines the global administrative state (enable or disable) using RF profiles.
- The AP manages communication between the Wi-Fi chip, the IoT chip, and the IOx application.
- The IOx application, such as those for ESL, requests IoT radio access and provides specific IoT performance counters.

Summary

The process involves these stages:

- Administrative Configuration: The controller sends the desired coexistence state to the AP.
- Application Subscription: After installation, the IOx application establishes gRPC connection to the AP and subscribes to the coexistence service.
- Enablement Request: The IOx application asks the AP to enable coexistence on the IoT chip.
- Priority Verification: The AP checks the administrative state from the controller and, if enabled, activates coexistence on the Wi-Fi and IoT chips.
- Status Synchronization: The IOx application confirms coexistence is enabled on the IoT chip, and the AP reports the 'Enabled' state to the controller.
- Periodic Reporting: The AP collects and forwards IoT statistics from the IOx application to the controller.

Workflow

When the administrative and application states are aligned, the system reliably transmits both Wi-Fi and IoT data without requiring manual intervention.

Configuration priority for Wi-Fi-IoT coexistence

This section explains the configuration priority details for Wi-Fi-IoT coexistence.

Controller configuration has higher priority than IOx application requests.

- If you disable coexistence on the controller, the AP disables the feature on the Wi-Fi chip and instructs the IOx application to disable the feature on the IoT chip, regardless of the IOx application's requirements.
- The IOx application can only enable coexistence if the administrative state in the AP's RF profile is set to Enabled.

Create an RF profile for Wi-Fi-IoT coexistence (CLI)

Use this procedure to create an RF profile for Wi-Fi-IoT coexistence using commands.

Provide a consistent RF environment that supports both Wi-Fi and IoT devices by defining an appropriate RF profile using commands.

RF profiles allow you to manage and tune radio parameters for different deployment needs, such as ensuring reliable operation of Wi-Fi and IoT devices in the 2.4 GHz band.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure Cisco AP and 802.11 parameters.

   Example

   ```
   Device(config)# ap dot11
   ```

3. Configure 802.11b parameters.

   Example

   ```
   Device(config)# ap dot11 24ghz
   ```

4. Set the RF-profile name and specify the name of the RF profile to configure.

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile default-rf-profile
   ```

5. Specify and enter the description of the RF profile.

Example

```
Device(config-rf-profile)# description description-detail
```

6. Negate a command. Shut down the profile and disable network.

Example

```
Device(config-rf-profile)# no shutdown
```

7. Exit the sub-mode.

Example

```
Device(config-rf-profile)# exit
```

Configure Wi-Fi-IoT coexistence (CLI)

Use this procedure to configure Wi-Fi-IoT coexistence using commands.

Enable coexistence between Wi-Fi and IoT radios to ensure reliable operation and minimize interference on supported Cisco APs using commands.

Wi-Fi-IoT coexistence allows the AP to support both Wi-Fi and IoT devices simultaneously on the 2.4 GHz band.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure Cisco AP and 802.11 parameters.

Example

```
Device(config)# ap dot11
```

3. Configure 802.11b parameters.

Example

```
Device(config)# ap dot11 24ghz
```

4. Set the RF-profile name and specify the name of the RF profile to configure.

Example

```
Device(config)# ap dot11 24ghz rf-profile default-rf-profile
```

5. Configure the RF Profile IoT settings.

   Example

   ```
   Device(config-rf-profile)# iot
   ```

6. Configure Wi-Fi-IoT radio coexistence.

   Example

   ```
   Device(config-rf-profile)# iot coexistence
   ```

7. Exit the sub-mode.

   Example

   ```
   Device(config-rf-profile)# exit
   ```

Tag the RF profile to an AP (CLI)

Use this procedure to tag the RF profile to an AP using commands.

Assign a specific RF profile to customize the radio configuration of an AP using commands.

Perform this task when you need to apply a distinct RF profile to a particular AP for more granular wireless control.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure wireless and tag parameters.

   Example

   ```
   Device(config)# wireless tag
   ```

3. Configure and enter the name of the RF tag.

   Example

   ```
   Device(config)# wireless tag rf default-rf-tag
   ```

4. Configure and name the dot11b policy.

   Example

   ```
   Device(config-wireless-rf-tag)# 24ghz-rf-policy default-dot11b-policy
   ```

5. Exit the sub-mode.

   Example

```
Device(config-wireless-rf-tag)# exit
```

6. Configure Cisco AP and enter the ethernet MAC address of the AP.

   Example

```
Device(config)# ap 9.12.15
```

7. Map a RF tag to the AP and enter the name of the RF tag.

   Example

```
Device(config-ap-tag)# rf-tag default-rf-tag
```

8. Exit the sub-mode.

   Example

```
Device(config-ap-tag)# exit
```

Verify Admin state on RF profile

This section explains how to verify Admin state on RF profile.

Use this command to verify the Admin state on RF profile.

- **show ap rf-profile name <RF_PROFILE> detail**

To verify the Admin state on RF profile, enter this command from the console:

```
Device# show ap rf-profile name iot-coex-custom-test-profile detail

Description                       : custom RF profile for IoT COEX testing
RF Profile Name                   : iot-coex-custom-test-profile

Verify coexistence configuration applied to an AP on controller

This section explains how to verify coexistence configuration applied to an AP on controller.

Use this command to verify coexistence configuration applied to an AP on controller.

- **show ap name <AP_NAME>config general | include IOT**

To verify the coexistence configuration applied to an AP on controller, enter this command from the console:

```
Device# show ap name AP8C88.8152.CEE0 config general
Cisco AP Name   : AP8C88.8152.CEE0
================================================

Cisco AP Identifier                             : 940d.4b9c.24e0

46 Smart Spaces - AnyLocate capabilities

Topics:

- AnyLocate feature set

AnyLocate feature set

Introduces the AnyLocate feature set, outlining capabilities for enhancing indoor location services using UWB and Wi-Fi FTM, and details technologies and workflows for indoor wayfinding, asset tracking, and AP auto-locate across supported Cisco APs.

AnyLocate capabilities are a suite of features that

- enhance indoor location services
- leverage technologies like ultra-wideband (UWB) and Wi-Fi fine timing measurement (FTM), and
- enable precise indoor wayfinding and asset tracking.

AnyLocate aims to transform the network into a sensor, eliminating the need for additional sensors or gateways by utilizing APs to facilitate location services. This umbrella term encompasses various location-based functionalities, including client location, RFID tags, BLE tags, AP auto-locate, UWB based indoor wayfinding and asset tracking.

Key features:

Indoor Wayfinding: Provides turn-by-turn directions within a building, similar to GPS for outdoor navigation.

Asset Tracking: Monitors the location of assets equipped with tracking tags.

AP Auto-locate: Automatically places APs on network maps using FTM and UWB based inter-AP ranging and GNSS data.

Wi-Fi fine timing measurement

Wi-Fi fine timing measurement (FTM) is a 802.11 standard feature that

- allows devices to measure their distance from Wi-Fi APs
- enhances indoor location accuracy, and
- uses time-stamped signal exchanges for ranging.

FTM improves upon traditional Wi-Fi signal strength (RSSI) based location by using precise time-stamping to calculate distances more accurately.

Supported APs

- Wi-Fi 6: Cisco Catalyst 9130 and 9120 Series APs
- Wi-Fi 6E APs
- Wi-Fi 7 APs

> **Note**
>
> For more information, check the Infrastructure Feature Matrix (IOS XE) tables for Wi-Fi 6 and Wi-Fi 7 APs.

Indoor wayfinding

Indoor wayfinding is a highly sought-after feature that

- allows clients to compute their own location within a building
- provides turn-by-turn directions to a desired destination, and

- functions as an indoor equivalent to outdoor GPS navigation.

Indoor wayfinding operates using these protocols.

- Client-side computation: The client device computes its own location.
- Technology leverage: Utilizes UWB DL-TDOA and Wi-Fi FTM for precise positioning.

Asset tracking

Asset Tracking is a feature that

- enables the precise monitoring of physical assets equipped with location tags
- leverages ultra-wideband (UWB) and bluetooth low energy (BLE) technologies, and
- allows the network infrastructure to compute and display the asset's location.

Unlike wayfinding, where the client computes its own location, asset tracking involves the network infrastructure actively listening for signals from specialized tags attached to assets. The network then calculates the tag's position, making it ideal for inventory management, equipment location, and other operational use cases.

Asset tracking operates using these protocols.

- Tag-initiated blinks: UWB-enabled tags periodically transmit short "blinks."
- Network-side listening: APs listen for these blinks, record their reception timestamps, and send this data to a central location engine.
- Infrastructure computation: The network infrastructure computes the tag's precise location based on the time differences of arrival at multiple APs.
- Hybrid tag support: Tags often combine BLE for onboarding and traditional location, with UWB for higher accuracy when available.

Feature history for Smart Spaces - AnyLocate capabilities

This section describes the feature history details for the Smart Spaces - AnyLocate capabilities feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 59: Feature history for Smart Spaces - AnyLocate capabilities

Feature Name	Release Information	Feature Description
Smart Spaces - AnyLocate capabilities	Cisco IOS XE 17.18.2	This is a suite of features that enhance indoor location services leveraging technologies like ultra-wideband (UWB), Wi-Fi fine timing measurement (FTM), and enable precise indoor wayfinding and asset tracking.

Prerequisites for asset tracking

This section describes the prerequisites for asset tracking.

There are four very basic device level prerequisites for asset tracking.

- Enable the global configuration knob for ranging.
- Enable UWB radio in the AP profile (the default setting is enabled).
- Allow and ensure a functional gRPC connection to Cisco Spaces Connector.
- Add the AP to the Cisco Spaces floor map and enable IoT services.

> **Note**
>
> Enabling IoT services through Cisco Spaces Connect feature is not supported yet.

After you meet these prerequisites, go to Cisco Spaces to enable the asset tracking feature, onboard tags, and use the detect and locate functions to track assets.

To verify the prerequisites for asset tracking, check Verify the prerequisites for asset tracking on page 684.

Time difference of arrival (TDOA)

This topic describes time difference of arrival (DOA) details.

Time difference of arrival (TDOA) operates in two ways

- Downlink time difference of arrival
- Uplink time difference of arrival

Downlink time difference of arrival (DL-TDOA)

Downlink time difference of arrival (DL-TDOA) is a UWB-based positioning method that

- allows client devices to compute their own location
- leverages time-synchronized UWB signals transmitted by APs, and
- ensures client privacy because location computation occurs on the device.

In a DL-TDOA system, APs transmit time-stamped UWB signals. Client devices passively listen to these signals, measure the time differences of arrival from multiple APs, and use this information to calculate their precise indoor position. This method is highly scalable and ensures user privacy because the network does not compute or store the client's location.

Uplink time difference of arrival (UL-TDOA)

Uplink time difference of arrival (UL-TDOA) is a UWB-based positioning method that

- enables the network infrastructure to compute the location of tracking tags
- relies on tags periodically transmitting UWB blinks, and
- is primarily used for asset tracking applications.

In a UL-TDOA system, UWB-enabled tags (attached to assets) periodically transmit short "blinks." APs listen to these blinks, record their reception timestamps, and forward this data to a central location engine. The network infrastructure then computes the tag's precise location based on the time differences of arrival at multiple APs.

Automatic reclustering for clock synchronization

This topic describes automatic reclustering for clock synchronization details.

Summary

Automatic reclustering for clock synchronization is the automated process of reconfiguring the UWB network's clusters and roles when an AP joins, leaves, or undergoes configuration changes, ensuring continuous and optimized location services.

- Wireless LAN Controller : Detects AP status changes and initiates reclustering requests.
- Cisco Spaces: Receives reclustering requests, initiates AP to AP ranging over UWB if necessary, computes new cluster configurations, and pushes them to the controller.
- APs: Apply new cluster configurations and participate in UWB location services.

Workflow

Reclustering behavior helps you anticipate network adaptation when APs change.

Prerequisites for wayfinding configurations

This topic describes the prerequisites for wayfinding configurations.

Ensure these prerequisites are met for UWB wayfinding functionality.

- Cisco Spaces integration: The controller must be onboarded to Cisco Spaces using a connector.
- AP placement on maps: Place all APs accurately on a map and associate them with a floor map in Cisco Spaces.
- Geo-coordinates: Enter geo-coordinates for each AP. Using AP Autolocate is preferred.
- Height and floor level: Record each AP’s height above the floor and specify its floor level.
- WLAN beacon broadcast: Enable beacon broadcast for at least one WLAN on each AP to support UWB Out-of-Band (OOB) communication with mobile devices.
- UWB coverage density: Deploy APs so that each AP covers 800 to 1000 square feet and provides adequate UWB coverage.

> **Note**
>
> Perform a proper RF design. Position each AP with equal importance as the AP density.

Impact of AP downtime on location services

This topic describes impact of AP downtime on location services.

An AP going down can affect UWB location service coverage.

- Localized blackout: If an AP goes down in your environment, you may lose location services in that area.
- Coverage resilience: In the event that one AP in your deployment becomes non-operational while four other anchors remain active, your location services continue to function. If there are fewer than four anchors in a specific area, computed location might be degraded or inaccurate.
- Maintenance window: Expect AP downtime during maintenance windows or network events. The system automatically recovers by reclustering when these events occur.

Enable UWB wayfinding (GUI)

Use this procedure to enable UWB wayfinding using the GUI.

Activate UWB wayfinding to enhance location services on an AP.

Before you begin

UWB must be enabled to proceed with this task.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Select the **AP Join Profile**.
3. Click on the **Geolocation** tab.
4. In the **Ultra-Wide Band (UWB)** section, toggle the button to enable **UWB Wayfinding**.
5. The **UWB Wayfinding Block Duration** value by default is one second.

Enable UWB wayfinding (CLI)

Use this procedure to enable UWB wayfinding using commands.

Enable UWB wayfinding and configure its block duration on a wireless AP profile using commands.

Procedure

1. Enter global configuration guide.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile1
   ```

3. Enable geolocation UWB wayfinding.

   Example

   ```
   Device(config-ap-profile)# [no] geolocation uwb wayfinding
   ```

   Use the **no** form of the command to disable UWB wayfinding.

4. Configure the geolocation UWB wayfinding block duration.

   Example

   ```
   Device(config-ap-profile)# geolocation uwb wayfinding block-duration 1second
   ```

The **UWB Wayfinding Block Duration** value by default is one second. The **UWB Wayfinding Block Duration** has two values: one second and 500 ms.

Configure height above the floor (GUI)

Use this procedure to configure height above the floor using the GUI.

Set the physical mounting height of an AP in centimeters as part of the AP provisioning process using the GUI.

Use this task during bulk AP provisioning to ensure accurate floor mapping and optimal wireless coverage by specifying a realistic height above floor.

Procedure

1. Choose **Configuration** > **Wireless** > **Bulk AP Provisioning**.
2. Click on **Select a workflow to create a AP Provisioning task.**
3. Select the AP and click **Next**.
4. In the **Floor** section, enter the **Height Above Floor (centimeters)** value.
   The **Height Above Floor (centimeters)** value's valid range is from 1 to 4000.
5. Click **Next**.

What to do next

To verify the configuration, check Verify AP location information on page 684.

Configure height above the floor (CLI)

Use this procedure to configure height above the floor using commands.

Specify the height of an AP above the floor to improve the accuracy of location services using commands.

The height above the floor (HATF) information is crucial for 3D location computations, especially for wayfinding and asset tracking use cases. This configuration can be done per AP.

Before you begin

- Ensure the AP is operational and managed by the controller.
- Know the precise height of the AP from the floor in centimeters.

Procedure

Configure the geolocation height above the floor for a Cisco AP.

Example

```
Device# ap name cisco-ap-name geolocation height-above-the-floor 1-4000
```

The valid range is from 1 to 4000 cm. Use the **no** form of the command to disable height above the floor for a Cisco AP.

The AP's height above the floor is set for use by location services.

What to do next

To verify the configuration, check Verify AP location information on page 684.

Verify AP UWB wayfinding status

This section provides the verifying AP UWB wayfinding status details.

Use these commands to verify the status of AP UWB wayfinding.

- **Device# show ap name <ap_name> geolocation uwb wayfinding**
- **Device# show ap geolocation uwb wayfinding detail**
- **Device# show ap geolocation uwb wayfinding status**
- **Device# show ap geolocation uwb wayfinding group <group name>**

To verify the AP geolocation UWB wayfinding, enter this command from the console:

```
Device# show ap name <ap_name> geolocation uwb wayfinding

AP MAC Address: f0d8.054c.12e0
Group ID: new_curl_group1
Status: Active
Number of Clusters: 1
Role: Initiator
Round Index: 0
Number of Responder Anchor: 1
Responder MAC    Slot Index
--------------------------
ecf4.0c92.b340   1
```

To verify the AP geolocation UWB wayfinding detail when AP is active, enter this command from the console:

```
Device# show ap geolocation uwb wayfinding detail
AP Name AP MAC Site Tag Group ID Status Block
Duration
NAlpine2 ecf4.0c92.b340 default-site-tag new_curl_group Active 1sec
NAlpine3 ecf4.0c92.b980 default-site-tag new_curl_group Active 1sec
NAlpine1 ecf4.0c9c.bd60 default-site-tag new_curl_group Active 1sec
NZealand1 f0d8.054c.12e0 default-site-tag new_curl_group Active 1sec
```

To verify the AP geolocation UWB wayfinding detail when the AP is in paused state, enter this command from the console:

```
Device# show ap geolocation uwb wayfinding detail
AP Name AP MAC Site Tag Group ID Status Block
Duration
NAlpine2 ecf4.0c92.b340 default-site-tag new_curl_group Paused 1sec
NAlpine3 ecf4.0c92.b980 default-site-tag new_curl_group Paused 1sec
NAlpine1 ecf4.0c9c.bd60 default-site-tag new_curl_group Paused 1sec
NZealand1 f0d8.054c.12e0 default-site-tag new_curl_group Paused 1sec
```

To verify the AP geolocation UWB wayfinding detail when the AP is in pending state, enter this command from the console:

```
Device# show ap geolocation uwb wayfinding detail
AP Name AP MAC Site Tag Group ID Status Block
Duration
NAlpine2 ecf4.0c92.b340 default-site-tag new_curl_group Pending 1sec
NAlpine3 ecf4.0c92.b980 default-site-tag new_curl_group Pending 1sec
NAlpine1 ecf4.0c9c.bd60 default-site-tag new_curl_group Pending 1sec
NZealand1 f0d8.054c.12e0 default-site-tag new_curl_group Pending 1sec
```

To verify the AP geolocation UWB wayfinding status, enter this command from the console:

```
Device# show ap geolocation uwb wayfinding status
Group-ID                        Clustered APs State        Active APs

1760584021797-1                 6             Configured   6
```

To verify the AP geolocation UWB wayfinding group, enter this command from the console:

```
Device# show ap geolocation uwb wayfinding group <group name>
Group ID: 1760584021797-1
Max Round: 7
Cluster List
Round Initiator Anchor                 Stratum Parent Anchor
  List of Responder Anchors (Slot-Index:Responder)

0     Alpine3                          0
  1:Zealand1 2:Alpine2 3:Alpine1 4:Alpine4 5:Zealand2
```

Verify AP UWB asset-tracking status

This section provides the verifying AP UWB asset-tracking status details.

Use these commands to verify the status of AP UWB asset-tracking.

- **Device# show ap name <ap_name> geolocation uwb asset-tracking**
- **Device# show ap geolocation uwb asset-tracking status**
- **Device# show ap geolocation uwb asset-tracking detail**

To verify the AP geolocation UWB asset-tracking, enter this command from the console:

```
Device# show ap name <ap_name> geolocation uwb asset-tracking

AP MAC Address: f0d8.054c.12e0
Group ID: ABC1231
Status: Active
Sync slot index: 0
Primary: 1
RX Bitmap: 0X00000000FFFFFFFF
```

To verify the AP geolocation UWB asset-tracking status, enter this command from the console:

```
Device# show ap geolocation uwb asset-tracking status

Group-ID                        Clustered APs State        Active APs

------------------------------------------------------------------------

ABC1231                         4             Configured   4
ne2 3:Alpine1 4:Alpine4 5:Zealand2
```

To verify the AP geolocation UWB asset-tracking detail, enter this command from the console:

```
Device# show ap geolocation uwb asset-tracking detail
```

```
AP Name                          AP MAC           Site Tag
      Group ID                         Status

_____________________________________________________________________________________

NAlpine2                         ecf4.0c92.b340   default-site-tag
      ABC1231                          Active

NAlpine3                         ecf4.0c92.b980   default-site-tag
      ABC1231                          Active

NAlpine1                         ecf4.0c9c.bd60   default-site-tag
      ABC1231                          Active

NZealand1                        f0d8.054c.12e0   default-site-tag
      ABC1231
```

Verify AP location information

This section provides verifying AP location information details.

Verify AP location information for these parameters:

- Verify height above the floor and latitude and longitude parameters from Cisco Spaces autoplacement or on the controller's console or GUI.

To verify height above the floor and latitude and longitude parameters from Cisco Spaces autoplacement or on the controller's console or GUI, enter these commands:

```
Device# ap name <ap_name> geolocation coordinate latitude longitude

Device# show ap name <ap_name> geolocation detail

AP Name                          : Alpine1
GNSS present                     : Yes
Location type                    : Ellipse
 HDOP                            : 0.000000
 Source                          : GNSS
 Center ellipse - longitude      : -121.928826
 Center ellipse - latitude       : 37.407565
 Ellipse major-axis (meters)     : 86
 Ellipse minor-axis (meters)     : 86
 Ellipse orientation             : 0.000000
 Last update                     : 12/03/2025 22:32:15
Height                           : NA
Height above the floor (cms)     : 200
```

Verify the prerequisites for asset tracking

This section provides the verifying the prerequisites for asset tracking details.

Verify the prerequisites for asset tracking for these parameters:

- Enable the global configuration knob for ranging.

- Enable UWB radio in the AP profile (the default setting is enabled).
- Allow and ensure a functional gRPC connection to Cisco Spaces Connector.
- Verify the controller to connector connection status

To enable the global configuration knob for ranging, use this command: **Device(config)# ap geolocation derivation ranging**

To check the UWB radio enablement in the AP profile, see Enable UWB wayfinding (GUI) on page 680 or Enable UWB wayfinding (CLI) on page 680.

Allow and ensure a functional gRPC connection to Cisco Spaces Connector by checking the controller connector connection.

To verify the controller to connector connection status, enter this command:

```
Device# show telemetry connection all
Telemetry connections

Index Peer Address               Port  VRF Source Address              State
    State Description
----- ------------------------- ----- --- ------------------------- ----------
 --------------------
    0 70.0.0.132                  8184 0   70.0.0.2                   Active
    Connection up
    1 70.0.0.132                  8004 0   70.0.0.2                   Active
    Connection up
  395 172.19.20.125             25103 1 M 172.20.209.40              Connecting
 Connection request made to transport handler
```

IoT service enablement is done from Cisco Spaces.

Part VI

Radio Resource Management

Topics:

- Radio Resource Management
- Coverage Hole Detection
- Optimized Roaming
- Cisco Flexible Radio Assignment
- XOR Radio Support
- Cisco Receiver Start of Packet
- Client Limit
- IP Theft
- Unscheduled Automatic Power Save Delivery
- Target Wake Time
- Enabling USB Port on Access Points
- Dynamic Frequency Selection
- Cisco Access Points with Tri-Radio
- Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard
- Antenna Disconnection Detection
- Neighbor Discovery Protocol Mode on Access Points
- 6-GHz Band Operations

47 Radio Resource Management

Topics:

- Radio resource management
- How to configure RRM
- Monitor RRM parameters and RF group status
- Event-Driven Radio Resource Management
- Rogue detection - rogue channel width

Radio resource management

Introduces radio resource management, covering real-time RF parameter control, AP monitoring, automated optimization, and key functions like radio resource monitoring, power control, dynamic channel assignment, coverage hole detection, and RF grouping to enhance wireless network performance..

A Radio Resource Management (RRM) is a system that

- consistently manages real-time RF parameters of a wireless network
- monitors associated APs for traffic load, interference, noise, coverage, and other metrics,
- performs critical functions like radio resource monitoring, power control transmission, dynamic channel assignment, and coverage hole detection and correction.

Feature history

Table 60: Feature history table for radio resource management

Feature name	Release information	Feature description
Radio resource management	Cisco IOS XE 16.10.1	Radio Resource Management (RRM) is a feature that automates and optimizes the management of radio frequencies in a wireless network. It enables continuous monitoring of access points (APs) for metrics such as traffic load, interference, noise, and coverage.

Functions of radio resource management

- Radio Resource Monitoring: Ensures optimal allocation of network resources.
- Power Control Transmission: Adjusts power levels to maintain network performance.
- Dynamic Channel Assignment: Allocates channels dynamically to reduce interference and optimize network performance.
- Coverage Hole Detection and Correction: Identifies and rectifies gaps in coverage to ensure consistent connectivity.
- RF Grouping: Groups RF resources effectively to manage interference and optimize performance.

Radio resource monitors

Radio resource monitor details.

Radio resource monitor is a system that

- detects and configures new devices and APs automatically
- adjusts associated APs for optimal coverage and capacity, and
- supports noise and interference monitoring.
- APs scan all the valid channels for the country of operation as well as for channels available in other locations.
- The APs in local mode go *offchannel* for a period not greater than 70 ms to monitor these channels for noise and interference.

- Packets collected during this time are analyzed to detect rogue APs, rogue clients, ad-hoc clients, and interfering APs.
- In the presence of voice traffic or other critical traffic (in the last 100 ms), APs can defer off-channel measurements. The APs also defer off-channel measurements based on the WLAN scan priority configurations.
- Each AP spends only 0.2 percent of its time off channel. This activity is distributed across all the APs so that adjacent APs are not scanning at the same time, which could adversely affect wireless LAN performance.

Mobility controller and mobility agent

Radio frequency groups

A radio frequency group is a collection of controllers that

- coordinate RRM globally
- support separate networks for 2.4 GHz and 5 GHz networks, and
- optimize network calculations on a per-radio basis.

Clustering Cisco Catalyst 9800 Series Wireless Controller into a single RF group enables the RRM algorithms to scale beyond the capabilities of a single Cisco Catalyst 9800 Series Wireless Controller.

RF group creation

Create an RF group using these parameters:

- User-configured RF network name.
- Neighbor discovery performed at the radio level.
- Country list configured on the controller.

RF grouping function run between controllers .

> **Note**
>
> RF groups and mobility groups are similar, in that, they both define clusters of controllers , but they are different in terms of their use. An RF group facilitates scalable, system-wide dynamic RF management, while a mobility group facilitates scalable, system-wide mobility and controller redundancy.

RF neighborhood

APs periodically send out neighbor messages over the air. APs using the same RF group name validate messages from each other.

When APs on different controllers hear validated neighbor messages at a signal strength of -80 dBm (or stronger), the controllers dynamically form an RF neighborhood in auto mode. In static mode, the leader is manually selected and the members are added to the RF Group.

RF group leader

Analyzes real-time radio data collected by the system, calculating the power and channel assignments.

An RF group leader is a designated device that

- analyzes real-time radio data collected by the system

- calculates power and channel assignments, and
- sends them to each controller in the RF group.

The RRM algorithms ensure system-wide stability, and restrain channel and power scheme changes to the appropriate local RF neighborhoods.

RF Group Leader is selected based on the controller with the greatest AP capacity (platform limit). If multiple controllers have the same capacity, the leader is selected based on the Group ID, which is a combination of the management IP address, AP capacity, random number, and so on. The one with the highest Group ID is selected as the leader.

RF Group Leader can be configured in two ways as follows:

- Auto Mode: In this mode, the members of an RF group elect an RF group leader to maintain a *primary* power and channel scheme for the group. The RF grouping algorithm dynamically chooses the RF group leader and ensures that an RF group leader is always present. Group leader assignments can and do change (for instance, if the current RF group leader becomes inoperable or RF group members experience major changes).
- Static Mode: In this mode, a user selects a controller as an RF group leader manually. In this mode, the leader and the members are manually configured and fixed. If the members are unable to join the RF group, the reason is indicated. The leader tries to establish a connection with a member every minute if the member has not joined in the previous attempt.

Note

- When a controller becomes both leader and member for a specific radio, you get to view the IPv4 and IPv6 address as part of the group leader.

  When a Controller A becomes a member and Controller B becomes a leader, the Controller A displays either IPv4 or IPv6 address of Controller B using the address it is connected.

  So, if both leader and member are not the same, you get to view only one IPv4 or IPv6 address as a group leader in the member.

Pinning and cascading

If Dynamic Channel Assignment (DCA) needs to use the worst-performing radio as the single criterion for adopting a new channel plan, it can result in pinning or cascading problems.

The main cause of both pinning and cascading is that any potential channel plan changes are controlled by the RF circumstances of the worst-performing radio. The DCA algorithm does not do this; instead, it does the following:

- Multiple local searches: The DCA search algorithm performs multiple local searches initiated by different radios in the same DCA run rather than performing a single global search that is driven by a single radio. This change addresses both pinning and cascading, while maintaining the desired flexibility and adaptability of DCA and without jeopardizing stability.
- Multiple Channel Plan Change Initiators (CPCIs): Previously, the single worst radio was the sole initiator of a channel plan change. Now each radio in an RF group is evaluated and prioritized as a potential initiator. Intelligent randomization of the resulting list ensures that every radio is eventually evaluated, which eliminates the potential for pinning.
- Limiting the propagation of channel plan changes (Localization): For each CPCI radio, the DCA algorithm performs a local search for a better channel plan, but only the CPCI radio itself and its one-hop neighboring access points are actually allowed to change their current transmit channels. The impact of an access point triggering a channel plan change is felt only to within two RF hops from that access point, and the actual channel plan changes are confined to within a one-hop RF neighborhood. Because this limitation applies across all CPCI radios, cascading cannot occur.

- Non-RSSI-based cumulative cost metric: A cumulative cost metric measures how well an entire region, neighborhood, or network performs with respect to a given channel plan. The individual cost metrics of all the access points in that area are considered in order to provide an overall understanding of the channel plan's quality. These metrics ensure that the improvement or deterioration of each single radio is factored into any channel plan change. The objective is to prevent channel plan changes in which a single radio improves, but at the expense of multiple other radios experiencing a considerable performance decline.

The RRM algorithms run at a specified updated interval, which is 600 seconds by default. Between update intervals, the RF group leader sends keepalive messages to each of the RF group members and collects real-time RF data.

Note

Several monitoring intervals are also available. See the Configuring RRM section for details.

RF grouping failure reason codes

RF Grouping failure reason codes and their explanations are listed below:

Table 61: RF Grouping Failure Reason Codes

Reason Code	Description
1	Maximum number (20) of controllers are already present in the group.
2	If the following conditions are met: • The request is from a similar powered controller and, • Controller is the leader for the other band, OR • Requestor group is larger.
3	Group ID do not match.
4	Request does not include source type.
5	Group spilt message to all member while group is being reformed.
6	Auto leader is joining a static leader, during the process deletes all the members.
9	Grouping mode is turned off.
11	Country code does not match.
12	Controller is up in hierarchy compared to sender of join command (static mode). Requestor is up in hierarchy (auto mode).
13	Controller is configured as static leader and receives join request from another static leader.
14	Controller is already a member of static group and receives a join request from another static leader.
15	Controller is a static leader and receives join request from non-static member.

Reason Code	Description
16	Join request is not intended to the controller. Controller name and IP do not match.
18	RF domain do not match.
19	Controller received a Hello packet at incorrect state.
20	Controller has already joined Auto leader, now gets a join request from static leader.
21	Group mode change. Domain name change from CLI. Static member is removed from CLI.
22	Max switch size (350) is reached

Additional Reference

Radio Resource Management White Paper: https://www.cisco.com/c/en/us/td/docs/wireless/controller/technotes/8-3/b_RRM_White_Paper/b_RRM_White_Paper_chapter_011.html

RF group name

An RF group name is a user-configured identifier assigned to a group of wireless LAN controllers that

- is sent to all the access points joined to the controller
- coordinate to perform Radio Resource Management (RRM) in a globally optimized manner,
- serves as a shared secret for generating hashed MIC in neighbor messages, and
- helps in avoiding RF interference and contention by ensuring system-wide RRM.

To create an RF group, you configure all the controllers to be included in the group with the same RF group name. If there is any possibility that an AP joined to a controller might hear RF transmissions from an AP on a different controller , you should configure the controller with the same RF group name.

If RF transmissions between APs can be heard, then system-wide RRM is recommended to avoid 802.11 interference and contention as much as possible.

Rogue AP detection in RF groups

Rogue AP Detection in RF Groups.

A rogue AP detection in an RF group is a wireless security feature that

- enables APs in the group to identify unauthorized neighboring APs
- uses beacon and probe-response frames to check for matching authentication elements, and
- automatically reports and records unauthorized devices for network monitoring and response.

After you create an RF group of controllers, you must configure connected access points to detect rogue APs. APs analyze neighbor messages for matching authentication elements. If a match is found, the AP authenticates the frame. If the authentication elements do not match, the AP reports the neighboring AP as rogue, logs its BSSID, and sends the log to the controller or embedded controller.

Secure RF groups

Secure RF groups enable encryption and security for RF grouping and RRM message exchanges over a DTLS tunnel.

Secure RF groups are a wireless LAN controller feature that

- encrypt radio frequency grouping and RRM message exchanges over a DTLS tunnel
- authenticate controllers using wireless management trust-point certificates during the DTLS handshake, and
- require all participating controllers to belong to the same mobility group.

RF profile configuration recommendation

RF group configuration recommendations.

The RF profile configuration recommendations are:

- Ensure that the country code configuration on both leader and member controllers match.
- RF grouping formation will not form if:
  - The group leader has IPv4 address and the group member has IPv6 address.
  - The group leader has IPv6 address and the group member has IPv4 address.
- Configure the IPv4 address on the group leader if RF grouping occurs between leader and member using IPv6 address.
- We recommend having the same RF profile configurations on the RF group leader and member controllers.
  - Since the RRM algorithms run on the group leader, they refer to the RF profile configurations of the leader controller. For example, additional channels in the member controller's list are not included by the group leader when it assigns a channel to the radio. Similarly, if there is a difference in configuration for DBS channel width between the leader and member controller, the algorithm only refers to the configurations of the group leader.
- For premises with over 20 controllers, we recommend that you have a common (non-default) RF network name for up to 20 controllers. The rest of the controllers can be mapped under different RF network names.
- For better network control, set your controller as static leader.

Examples: RF group configuration

RF Group Configuration examples.

These are examples of RF group name configuration.

```
Device# configure terminal
Device(config)# wireless rf-network test1
Device(config)# ap dot11 24ghz shutdown
Device(config)# end
Device# show network profile 5
```

This example demonstrates how to configure rogue AP sdetection within RF groups.

```
Device# ap name ap1 mode clear
Device# end
Device# configure terminal
Device(config)# wireless wps ap-authentication
Device(config)# wireless wps ap-authentication threshold 50
Device(config)# end
```

Transmit power control

A transmit power control is an automation algorithm that:

- increases and decreases an access point's power dynamically
- responds to changes in the RF coverage environment, and
- provides enough RF power to achieve the required coverage levels while avoiding channel interference.

This feature is different from coverage hole detection, which is primarily concerned with clients.

- TPC provides enough RF power to achieve the required coverage levels while avoiding channel interference between APs. We recommend that you select TPCv1; TPCv2 option is deprecated.
- With TPCv1, you can select the channel aware mode; we recommend that you select this option for 5 GHz, and leave it unchecked for 2.4 GHz.

Override the TPC algorithm with minimum and maximum transmit power settings

Override the TPC Algorithm with Minimum and Maximum Transmit Power Settings.

A Transmit Power Control (TPC) minimum and maximum transmit power setting is a wireless network configuration option that

- defines the allowed range of RF transmit powers for APs
- overrides the automatic power adjustment recommendations of the TPC algorithm, and
- applies settings globally to APs through RF profiles.

The TPC (Transmit Power Control) algorithm automatically balances RF power in various environments. Occasionally, site or architectural constraints require manually overriding TPC recommendations. With minimum and maximum power settings, you ensure APs do not exceed or fall below specific transmit powers, regardless of TPC or automatic adjustments or coverage hole detection.

Each AP model and each regulatory domain has its own allowed power levels. The increments vary: Cisco APs use 3 dB increments, but settings can be chosen in 1 dB increments and rounded.

To set the Maximum Power Level Assignment and Minimum Power Level Assignment, enter the maximum and minimum transmit power used by RRM in the fields in the **Tx Power Control** window. The range for these parameters is from -10 to 30 dBm. The minimum value cannot be greater than the maximum value; the maximum value cannot be less than the minimum value.

If you configure a maximum transmit power, RRM does not allow any access point attached to the controller, to exceed this transmit power level (whether the power is set by RRM TPC or by coverage hole detection). For example, if you configure a maximum transmit power of 11 dBm, no AP will transmit above 11 dBm unless the AP is configured manually.

Cisco APs support power level changes in 3 dB granularity. TPC Min and Max power settings allow for values in 1 dB increments. The resulting power level will be rounded to the nearest value supported in the allowed powers entry for the AP model and the current serving channel.

Each AP model has its own set of power levels localized for its regulatory country and region. Moreover, the power levels for the same AP model will vary based on the band and channel it is set to. For more information about Allowed Power Level versus Actual Power (in dBm), use the **show ap name <name> config slot <0|1|2|3>** command. This command displays the specific number of power levels, the allowed range of power levels, and the current power level setting on the AP.

Dynamic channel assignment

Dynamic Channel Assignment (DCA) minimizes adjacent channel interference between APs.

A dynamic channel assignment (DCA) is a wireless LAN management technique that

- automatically evaluates radio frequency (RF) conditions and network utilization
- dynamically allocates channels among APs to minimize interference and maximize performance, and
- continuously updates channel assignments based on system-wide RF analytics and policies.

Features of DCA

Features of DCA are:

- **Dynamic channel allocation**: DCA dynamically assigns channels to APs to avoid conflicts and interference, improving network capacity and performance. Two adjacent APs on the same channel can cause signal contention or collision. In a collision, data is not received by the AP. For example, reading an e-mail in a café can affect the performance of an AP in a neighboring business.

  Even though these are separate networks, someone sending traffic to the café on channel 1 can disrupt communication in an enterprise using the same channel. Devices can dynamically allocate AP channel assignments to avoid conflict and increase capacity and performance.

- **Channel reuse**: Efficiently reuses channels by assigning the same channel to APs that are physically far apart, maximizing scarce RF resources. In other words, channel 1 is allocated to a different AP far from the café, which is more effective than not using channel 1 altogether.

- **Adjacent channel separation**: The device's DCA capabilities are also useful in minimizing adjacent channel interference between APs.

  For example, two overlapping channels in the 802.11b/g band, such as 1 and 2, cannot simultaneously use 11 or 54 Mbps. By effectively reassigning channels, the device keeps adjacent channels separated.

Channel assignments

The device examines a variety of real-time RF characteristics to efficiently handle channel assignments.

- AP received energy: The received signal strength measured between each AP and its nearby neighboring AP. Channels are optimized to give you the highest network capacity.
- Noise: Noise can limit signal quality for your devices and APs. Increased noise reduces cell size and degrades user experience. By optimizing channels to avoid noise sources, the device helps you maintain coverage and system capacity. If a channel is unusable due to excessive noise, that channel can be avoided.
- 802.11 interference: Interference is any 802.11 traffic that is not a part of your wireless LAN, including rogue APs and neighboring wireless networks. Lightweight APs automatically scan all channels to detect interference sources. If the amount of 802.11 interference exceeds a predefined configurable threshold (the default is 10 percent), the AP sends an alert to the device. Using the RRM algorithms, the device may then dynamically rearrange channel assignments to increase system performance in the presence of the interference. Such an adjustment could result in adjacent lightweight APs being on the same channel, but this setup provides better performance than keeping APs on a channel made unusable by interference.

  In addition, if other wireless networks are present, the device shifts the usage of channels to complement the other networks. For example, if one network is on channel 6, an adjacent wireless LAN is assigned to channel 1 or 11. This arrangement increases the capacity of the network by limiting the sharing of frequencies. If a channel has virtually no capacity remaining, the device may choose to avoid this channel. In huge deployments in which all nonoverlapping channels are occupied, the device does its best, but you must consider RF density when setting expectations.

- Load and utilization: When utilization monitoring is enabled, capacity calculations can consider that some APs are deployed in ways that carry more traffic than other APs, for example, a lobby versus an engineering area. The device can then assign channels to improve the AP that has performed the worst. The load is taken into account when changing the channel structure to minimize the impact on the clients that are currently in the wireless LAN. This metric

keeps track of every AP's transmitted and received packet counts to determine how busy the APs are. New clients avoid an overloaded AP and associate to a new AP. This *Load and utilization* parameter is disabled by default.

The device combines this RF characteristic information with RRM algorithms to make system-wide decisions. Conflicting demands are resolved using soft-decision metrics that guarantee the best choice for minimizing network interference. The result is optimal channel configuration across three dimensions. APs located on different floors play an important role in your wireless LAN configuration.

RRM startup mode

The RRM startup mode is invoked under these conditions:

- In a single- device environment, the RRM startup mode is invoked after the device is upgraded and rebooted.
- In a multiple- device environment, the RRM startup mode is invoked after an RF Group leader is elected.
- You can trigger the RRM startup mode using the **ap dot11 {24ghz | 5ghz | 6ghz} rrm dca restart** command.

The RRM startup mode runs for 100 minutes (ten iterations at ten-minute intervals). The duration of the RRM startup mode is independent of the DCA interval, sensitivity, and network size. The startup mode consists of ten DCA runs with high sensitivity (making channel changes easy and sensitive to the environment) to converge to a steady-state channel plan. DCA continues to run at the specified interval and sensitivity after the startup mode is finished.

Dynamic bandwidth selection

Provides a smooth transition for various configurations while upgrading from 11n to 11ac.

Dynamic bandwidth selection is a wireless network algorithm that

- maximizes network throughput by dynamically varying the channel width during operation
- fine-tunes channel assignments by monitoring channel and Base Station Subsystem (BSS) statistics, and
- adapts to changes in network conditions, such as transitions from 11n to 11ac, and variable client mixes.

During upgrades from 11n to 11ac, dynamic bandwidth selection enables a smooth transition between configurations by adjusting channel widths and orientation (such as choosing between 40 MHz and 80 MHz bandwidths) in response to fast-changing wireless statistics.

Limitations for DCA

DCA limitations include the following items.

- DCA supports only 20-MHz channels in the 2.4-GHz band.
- In a Dynamic Frequency Selection (DFS)-enabled AP environment, enable the UNII2 channels option under the DCA channel to allow 100-MHz separation for the dual 5-GHz radios.
- The calculation methods for interference and channel utilization differ between 9120 (and older) AP models and the newer 916x and 917x AP models. The 9120 and older APs estimate interference and channel utilization using Wi-Fi data packets received from non-neighbor Wi-Fi sources during scanning. In contrast, the 916x and 917x APs use the radio chip vendor’s hardware-level snapshots to determine channel activity, providing improved accuracy over the older models.
- Use only nonoverlapping channels (1, 6, 11, and others) for reassigning channels to minimize interference.
- Channel change does not require you to shut down the radio.
- The DCA algorithm interval is set to one hour. However, the DCA algorithm always runs at the default interval of 10 minutes. Channel allocation occurs at 10-minute intervals for the first 10 cycles, and channel changes occur every 10 minutes as determined by the DCA algorithm. After these cycles, the DCA algorithm returns to the configured interval.

- Invoking channel update will not result in any immediate changes until the next DCA interval is triggered.
- If DCA or Transmit Power Control (TPC) is turned off on the RF group member, and automatic settings are enabled on the RF group leader, the channel or transmit power on the member changes according to the algorithm run on the RF group leader.

Coverage hole detection and correction

Details the coverage hole detection and correction algorithm, including alerting administrators to insufficient wireless coverage, discriminating between correctable and uncorrectable holes, and adjusting AP transmit power to mitigate coverage issues.

A coverage hole detection and correction algorithm is a wireless LAN management mechanism that

- identifies areas with insufficient radio coverage for reliable performance
- alerts administrators when access points fail to provide adequate coverage, and
- adjusts AP transmit power to mitigate correctable coverage holes.

If clients on a lightweight AP are detected at threshold levels such as RSSI, failed client count, percentage of failed packets, and number of failed packets that are lower than those specified in the RRM configuration, the AP sends a “coverage hole” alert to the device. The alert indicates that clients cannot connect to a usable AP because of poor signal coverage.

The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific AP.

The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level. Increasing downstream transmit power could increase interference in the network.

Cisco AI enhanced RRM

The AI Enhanced RRM is the next evolution of Cisco's Radio Resource Management (RRM).

A Cisco AI enhanced RRM is a wireless radio resource management technology that

- applies artificial intelligence and machine learning to optimize RF environments
- operates through distributed data collection from Cisco wireless controllers and cloud-based analytics, and
- automates and adapts RF parameter tuning for Cisco wireless networks.

The RRM runs as a service in a Cisco Catalyst 9800 Series Wireless Controller. The Cisco RRM manages the RF Group (the components making up the RF Network) based on dynamic measurements between every AP and its neighbors stored in a local database for the entire RF Group. At runtime, the RRM draws the last 10 minutes of the collected data, and gently optimizes based on the current network conditions.

The AI Enhanced RRM integrates the power of Artificial Intelligence and Machine Learning to the reliable and trusted Cisco RRM product family algorithms in the Cloud.

Note

The AI enhanced RRM is coordinated through the Cisco Catalyst Center (on-prem appliance) as a service. The current RRM sites are seamlessly transitioned to an intelligent centralized service. AI enhanced RRM along with other Cisco Catalyst Center services brings a host of new features with it.

Cisco AI Enhanced RRM operates as a distributed RRM service. RF telemetry is collected from the Cisco Access Points by the controller, and passed through the Catalyst Center to the Cisco AI Analytics Cloud where the data is stored. The RRM Algorithms run against this telemetry data stored in the cloud. AI analyzes the solutions, and passes any configuration change information back to the Catalyst Center . The Catalyst Center maintains the control connection with the enrolled controller and passes any individual AP configuration changes back to the APs.

Note

The RRM algorithms run in the cloud against the telemetry data available in the cloud.

The following RRM algorithms run in the cloud while the remaining work in the controller:

- DCA
- TPC
- DBS
- FRA

Cisco AI enhanced RRM supporting releases

The table covers the controller and Cisco Catalyst Center release versions that support Cisco AI Enhanced RRM support:

Table 62: Controller and Cisco Catalyst Center releases supporting Cisco AI enhanced RRM support

Controller release	Cisco Catalyst Center release	Cisco AI enhanced RRM support
Cisco IOS XE Cupertino 17.9.x	• Cisco Catalyst Center , Release 2.3.2 or Cisco Catalyst Center , Release 2.3.3 • Cisco Catalyst Center , Release 2.3.4	• 2.4GHz and 5GHz • 2.4GHz, 5GHz, and 6GHz
Cisco IOS XE Cupertino 17.8.x	• Cisco Catalyst Center , Release 2.3.2 Cisco Catalyst Center , Release 2.3.3 • Cisco Catalyst Center , Release 2.3.4	2.4GHz and 5GHz
Cisco IOS XE Cupertino 17.7.x	Cisco Catalyst Center , Release 2.3.2 or Cisco Catalyst Center , Release 2.3.3	2.4GHz and 5GHz

If the location of controller, and APs are provisioned previously, assigning a location enrolls the AI Enhanced RRM Services and the profile to be pushed to the controller. Thus, AI Enhanced RRM becomes the RF Group Leader for the subscribed controller.

For more information on the Cisco Catalyst Center, see Cisco Catalyst Center User Guide .

Restrictions

Restrictions for Radio Resource Management (RRM).

The restrictions for RRM are:

- The maximum number of APs supported in an RF group depends on the capacity of the controller platform acting as the RF group leader. For platform-specific RF-group limits, refer the C9800 Radio Resource Management Deployment Guide.
- If an AP tries to join the RF-group that already holds the maximum number of APs it can support, the device rejects the application and throws an error.
- Disabling all data rates for **default rf-profile** or **custom rf-profile** affects the ISSU upgrade and client join process after the software upgrade (ISSU or non-ISSU). To prevent this, you must enable at least one data rate (for example, **ap dot11 24 rate RATE_5_5M enable**) on the **default rf-profile** or **custom rf-profile**. We recommend that you enable the lowest data rate if efficiency is of prime concern.
- Keywords like **secure** are not permissible as RF group names.
- RRM grouping does not occur when an AP operates in a static channel that is not in the DCA channel list. The Neighbor Discovery Protocol (NDP) is sent only on DCA channels; therefore, when a radio operates on a non-DCA channel, it does not receive NDP on the channel.

How to configure RRM

Guides you through configuring neighbor discovery type, RF groups, static RF groups, transmit power control, 802.11 RRM parameters and 802.11 advanced RRM, using GUI steps and CLI commands for effective Radio Resource Management.

Configure neighbor discovery type (GUI)

Configure Neighbor Discovery Type using GUI.

Configure the Neighbor Discovery Type for your network devices by leveraging the GUI interface.

Use this task to set the Neighbor Discovery Type within the Radio Resource Management settings to enhance the network's ability to detect and manage neighbor devices efficiently.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM** .
2. On the **Radio Resource Management** page, click either the **5 GHz Band** , **2.4 GHz Band** or the **6 GHz Band** tab.
3. In the **General** tab, under each section enter the corresponding field details:
   a) Under the **Profile Threshold For Traps** section, enter the:
      1. **Interference Percentage**: The foreign interference threshold range is from 0 to 100 %. The default is 10 %.
      2. **Clients**: The client threshold range is from 1 to 75 clients. The default is 12.
      3. **Noise**: The foreign noise threshold range is from -127 dBm to 0dBm. The default is -70 dBm.

4. **Utilization Percentage**: The RF utilization threshold between 0 and 100 %. The default is 80 %.
5. **Throughput**: The average rate of successful messages delivery over a communication channel. Value ranges from 1000 to 10000000 bps. The default value is 1000000.

b) Under the **Noise/Interference/Rogue/CleanAir/SI Monitoring Channels** section, choose these options:

1. **Channel List** from the drop-down list:
   - All Channels
   - Country Channels
   - DCA Channels
2. **RRM Neighbor Discover Type** from the drop-down list:
   - **Transparent**: Packets are sent as is.
   - **Protected**: Packets are protected.
3. **RRM Neighbor Discovery Mode**:
   - **AUTO**: If the NDP mode configured is AUTO, the controller selects On-Channel as the NDP mode. The default is set as AUTO.
   - **OFF-CHANNEL**: If the NDP mode configured is Off-Channel, the controller selects Off-Channel as the NDP mode.

c) Under the **Monitor** section, set these options:

- **Neighbor Packet Frequency (seconds)**: Frequency (in seconds) in which the Neighbor Discovery Packets are sent. The default is 180 seconds.
- **Reporting Interval (seconds)**: The default is 180 seconds. Each channel dwell has to be completed within 180 seconds.
- **Neighbor Timeout factor**: Value in seconds used to determine when to prune access points from the neighbor list that have timed out. The default is 20 seconds.

4. Click **Apply** to save your configuration.

Neighbor discovery for your network devices is complete.

Configure neighbor discovery type (CLI)

Configure Neighbor Discovery Type using commands.

Specify how neighbor discovery packets are handled on each radio band.

Procedure

---

1. Enter global configuration mode.

   Example

```
Device# configure terminal
```

2. Configure the neighbor discovery type for the desired radio band.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm ndp-type {protected |
   transparent}
   ```

   The NDP types are:

   - **protected**: Use **protected** to encrypt discovery packets.
   - **transparent**: Use **transparent** to send packets as is (default).

3. Return to privileged EXEC mode by ending the configuration mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The neighbor discovery type for the specified band is set.

Configure RF groups

Configure RF Groups through either the GUI or the CLI.

RF groups are configured through either GUI or CLI. You can also configure RF groups through

> **Note**
>
> When the multiple-country feature is being used, all controllers intended to join the same RF group must be configured with the same set of countries, configured in the same order.

Configure RF group selection mode (GUI)

Configure RF Group Selection Mode using GUI.

Set the RF Group Selection Mode for a wireless controller to manage radio resource management (RRM) and group configuration.

Use this procedure when you need to designate or update the RF Group Selection Mode on your controller using the web interface.

Before you begin

Ensure you have administrator access to the wireless controller GUI.

To configure the RF Group Selection Mode, use the steps in this section:

Procedure

---

1. Choose **Configuration** > **Radio Configurations** > **RRM**.

2. On the **RRM** page, click the relevant band tab: either **6 GHz Band**, **5 GHz Band**, or **2.4 GHz Band**.
3. Click the **RF Grouping** tab.
4. Choose the appropriate **Group Mode** from these options:
   - Automatic: Sets the 802.11 RF group selection to automatic update mode.
   - Leader: Sets the 802.11 RF group selection to leader mode.
   - Off: Disables the 802.11 RF group selection.

   Note

   When AI Enhanced RRM is enabled on a controller and Cisco Catalyst Center is connected to a wireless network, Cisco Catalyst Center is assigned the group role as leader. Controllers managed by Cisco Catalyst Center with AI Enhanced RRM enabled are assigned the group role as remote members regardless of the group mode previously assigned. The **Group Role** field displays **Remote Member**, and the **Group leader** field displays the IP address of the Cisco Catalyst Center.

5. Save the configuration.

The controller applies the selected RF Group Selection Mode to the chosen bands.

Configure RF group selection mode (CLI)

Configure RF Group Selection Mode using commands.

Set the RF group selection mode for specific 802.11 radio bands on a Cisco device using CLI commands.

Use this procedure to configure how access points are grouped for RF management purposes by specifying the RF group selection mode for 2.4 GHz, 5 GHz, or (if supported) 6 GHz bands.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RF group selection mode for your 802.11 band.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm group-mode {auto | leader | off}
   ```

   - **auto**: Sets the 802.11 RF group selection to automatic update mode.
   - **leader**: Sets the 802.11 RF group selection to leader mode.
   - **off**: Disables the 802.11 RF group selection.

3. Configure RF group selection mode for 802.11 bands.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm group-mode {auto | leader
 | off}
```

- **auto**: Sets the 802.11 RF group selection to automatic update mode.
- **leader**: Sets the 802.11 RF group selection to leader mode.
- **off**: Disables the 802.11 RF group selection.

4. Exit configuration mode to return to privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The system applies the selected RF group selection mode to the specified 802.11 band.

Configure an RF group name (CLI)

Configure an RF Group Name using commands.

Set up a radio frequency (RF) group for wireless controllers. This action optimizes radio resource management.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Create an RF group. Enter a group name in ASCII format, up to 19 characters long. The name is case sensitive.

Example

```
Device(config)# wireless rf-network network-name
```

> **Note**
>
> Repeat this procedure for each controller you want to add to the RF group.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

You can also press **Ctrl-Z** to exit global configuration mode.

The RF group is created. Controllers in the group share RF information to optimize radio performance.

```
Device# configure terminal
Device(config)# wireless rf-network network1
Device(config)# end
Device# show network profile 100
```

Configure a secure RF group (CLI)

Configure a Secure RF Group using commands.

Set up a secure RF group for optimal wireless device communication and management.

With a secure RF group, your access points coordinate radio resources to improve network performance.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a secure RF group and enable the secure RF group functionality.

   Example

   ```
   Device(config)# wireless rf-network secure
   ```

3. Exit to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

4. Optional: Verify the RF group configuration and statistics for the desired frequency band , such as 2.4 GHz, 5 GHz, or 6 GHz.

   Example

   ```
   Device# show ap dot11 {24ghz | 5ghz | 6ghz} group
   ```

The secure RF group is created and operational on the selected wireless controller.

Configure members in an 802.11 static RF group (GUI)

Configure Members in an 802.11 Static RF Group using GUI.

Add controllers to a static RF group. This configuration enables coordinated radio management and optimizes wireless network performance.

When you configure static RF groups, you can manually designate RF group leaders and members. This approach supports predictable behavior and enhances control over radio resource management.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM** .
2. On the **RRM** page, click either the **6 GHz Band** , **5 GHz Band**, or **2.4 GHz Band** tab.
3. Click the **RF Grouping** tab.
4. Choose the appropriate **Group Mode** from these options:
   - **Automatic (default)**: Members of an RF group elect a leader to maintain a primary power and channel scheme. The RF grouping algorithm selects the group leader dynamically and ensures continuous leadership. Group leader assignments can change. For example, assignments change if the current leader becomes inoperable or if group members experience significant changes.
   - **Leader**: A device as an RF group leader, manually. In this mode, the leader and members are manually configured. Their assignments remain fixed. If a member is unable to join the RF group, the system indicates the reason. The system uses the member's management IP address and system name to request that the member join the leader. The leader attempts to connect with a member every minute if the member did not join during the previous attempt.
   - **Off**: No RF group is configured.
5. Under **Group Members** section, click **Add**.
6. In the **Add Static Member** window that is displayed, enter the controller name and the IPv4 or IPv6 address of the controller.
7. Click **Save & Apply to Device**.

The new member is added to the static RF group and joins the manually configured group for radio parameter coordination.

Configure members in an 802.11 static RF group (CLI)

Configure Members in an 802.11 Static RF Group using commands.

Define APs as members of a static RF group using the CLI, enabling coordinated radio management.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure members in an 802.11 static RF group.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm group-member group_name
   ip_addr
   ```

Set the group mode to leader to activate the group member.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

You can also press **Ctrl-Z** to exit global configuration mode.

The AP is added as a member of the 802.11 static RF group.

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm group-member Grpmem01 10.1.1.1
Device(config)# end
```

Configure transmit power control

-

Configure transmit power (GUI)

Configure Transmit Power using GUI.

Configure transmit power settings for wireless APs.

Procedure

---

1. Choose **Configuration** > **Radio Configurations** > **RRM** .
2. On the **6 GHz Band** , **5 GHz Band** , or **2.4 GHz Band** tab, click the **TPC** tab.
3. Choose one of these dynamic transmit power assignment modes:
   - **Automatic** (default): The transmit power is periodically updated for all APs that permit this operation.
   - **On Demand**: The transmit power is updated on demand. If you choose this option, you get to view the **Invoke Power Update Once** . Click **Invoke Power Update Once** to apply the RRM data successfully.
   - **Fixed**: No dynamic transmit power assignments occur and values are set to their global default.
4. Enter the maximum and minimum power level assignment on this radio. If you configure maximum transmit power, RRM does not allow any AP attached to the device to exceed this transmit power level. This applies whether the power is set by RRM TPC or by coverage hole detection.

   For example, if you configure a maximum transmit power of 11 dBm, then no AP would transmit above 11 dBm, unless the AP is configured manually. The range is from -10 dBm to 30 dBm.
5. In the **Power Threshold** field, enter the cutoff signal level used by RRM when determining whether to reduce an access point's power.

   The default value for this parameter varies depending on the TPC version you choose. For TPCv1, the default value is -70 dBm, and for TPCv2, the default value is -67 dBm. The default value can be changed when APs are transmitting at higher (or lower) than desired power levels. The range is from -80 to -50 dBm.

   Increasing this value (between -65 and -50 dBm) causes the APs to operate at higher transmit power rates. Decreasing the value has the opposite effect. In applications with a dense population of APs, it may be useful to decrease the threshold to -80 or -75 dBm in order to reduce the number of BSSIDs (APs) and beacons seen by the wireless clients. Some wireless clients might have difficulty processing a large number of BSSIDs or a high beacon rate and might exhibit problematic behavior with the default threshold.

6. Click **Apply** .

Transmit power settings are updated according to your configuration.

Configure Tx-power control threshold (CLI)

Configure the Tx-Power Control Threshold using commands.

Set the Tx-power control threshold to define the minimum received signal strength at which the device adjusts its transmit power.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the Tx-power control threshold used by RRM for auto power assignment.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm tpc-threshold
   threshold_value
   ```

   The range is from -80 dBm to -50 dBm.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   You can also press **Ctrl-Z** to exit global configuration mode.

The Tx-power control threshold is updated, enabling the device to adjust its transmit power according to the specified threshold.

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm tpc-threshold -60
Device(config)# end
```

Configure the Tx-power level (CLI)

Configure the Tx-Power Level using commands.

Set the transmit power level of the wireless AP to improve wireless coverage and signal strength.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the 802.11 Tx-power level.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz} rrm txpower {trans_power_level | auto
 | max | min | once}
```

The Tx-power parameters are:

- **trans_power_level**: Sets the transmit power level.
- **auto**: Enables auto-RF.
- **max**: Configures the maximum auto-RF Tx-power.
- **min**: Configures the minimum auto-RF Tx-power.
- **once**: Enables one-time auto-RF.

3. Configure the 802.11 6-GHz Tx-power level.

Example

```
Device(config)# ap dot11 6ghz rrm txpower trans_power_level auto
```

The Tx-power parameters are:

- *trans_power_level*: Sets the transmit power level. The range is 1 to 5.
- **auto**: Enables auto-RF.

> **Note**
>
> The 6-GHz band uses constant-PSD instead of constant-EIRP, which allows you to transmit at higher power as the channel width increases. The system derives the power levels based on the configured channel width. At higher power levels between 1 and 3, these power values exceed the limit for legacy rate frames, such as beacon frames. The beacon power does not change at higher levels in the 6-GHz band, unlike in the 2.4-GHz and 5-GHz bands.

4. **end**

Example

```
Device(config)# end
```

Return to privileged EXEC mode.

Configure 802.11 RRM parameters

-

Configure advanced 802.11 channel assignment parameters (GUI)

Configure Advanced 802.11 Channel Assignment Parameters using GUI.

Configure the RRM settings to optimize channel assignment for 802.11 wireless networks.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM** .
2. In the **DCA** tab, complete these details:
   a) Select a **Channel Assignment Mode** to specify the DCA mode:
      - **Automatic** (default): Causes the device to periodically evaluate and, if necessary, update the channel assignment for all joined APs.
      - **Freeze**: Causes the device to evaluate and update the channel assignment for all joined APs. If you choose this option, you get to view the Invoke Channel Update Once. Click **Invoke Channel Update Once** to apply the RRM data successfully.
      - **Off**: Turns off DCA and sets all AP radios to the first channel of the band, which is the default value. If you choose this option, you must manually assign channels on all radios.

   b) From the **Interval** drop-down list, choose the interval that tells how often the DCA algorithm is allowed to run. The default interval is 10 minutes.
   c) From the **Anchortime** drop-down list, choose a number to specify the time of day when the DCA algorithm must start. The options are numbers between 0 and 23 (inclusive) representing the hour of the day from 12:00 a.m. to 11:00 p.m.
   d) Check the **Avoid Foreign AP Interference** check box to cause the device's RRM algorithms to consider 802.11 traffic from foreign APs (those not included in your wireless network) when assigning channels to lightweight APs, or uncheck it to disable this feature. For example, RRM may adjust the channel assignment to have APs avoid channels close to foreign APs. By default, this feature is in enabled state.
   e) Check the **Avoid Cisco AP Load** check box to cause the device's RRM algorithms to consider 802.11 traffic from Cisco lightweight APs in your wireless network when assigning channels. For example, RRM can assign better reuse patterns to APs that carry a heavier traffic load. By default, this feature is in disabled state.
   f) Check the **Avoid Non-802.11a Noise** check box to cause the device's RRM algorithms to consider noise (non-802.11 traffic) in the channel when assigning channels to lightweight APs. For example, RRM may have APs avoid channels with significant interference from non-AP sources, such as microwave ovens. By default, this feature is in enabled state.
   g) Check the **Avoid Persistent Non-Wi-Fi Interference** check box to enable the device to take into account persistent non-Wi-Fi interference in DCA calculations. A persistent interfering device is any device from the following categories, which has been seen in the past 7 days - Microwave Oven, Video Camera, Canopy, WiMax Mobile, WiMax Fixed, Exalt Bridge. With **Avoid Persistent Non-Wi-Fi Interference** enabled, if a Microwave Oven is detected, that interference from the Microwave Oven is taken into account in the DCA calculations for the next 7 days. After 7 days, if the interfering device is not detected anymore, it is no longer considered in the DCA calculations.
   h) From the **DCA Channel Sensitivity** drop-down list, choose one of the following options to specify how sensitive the DCA algorithm is to environmental changes such as signal, load, noise, and interference when determining whether to change channels:
      - **Low**: The DCA algorithm is not particularly sensitive to environmental changes. The DCA threshold is 30 dB.
      - **Medium** (default): The DCA algorithm is moderately sensitive to environmental changes. The DCA threshold is 15 dB.

- **High**: The DCA algorithm is highly sensitive to environmental changes. The DCA threshold is 5 dB.

i) Set the **Channel Width** as required. You can choose the RF channel width as 20 MHz, 40 MHz, 80 MHz, 160 MHz, or Best. This is applicable only for 802.11a/n/ac (5 GHz) radio.

3. The **Auto-RF Channel List** section shows the channels that are currently selected. To select a channel, check the corresponding check box.

> **Note**
>
> If you disable the serving radio channel of the root AP from the **Auto-RF Channel List**, you will not be able to view the neighboring APs in the root APs.

4. In the **Event Driven RRM** section, check the **EDRRM** check box to run RRM when CleanAir-enabled AP detects a significant level of interference. If enabled, set the sensitivity threshold level at which the RRM is invoked, enter the custom threshold, and check the **Rogue Contribution** check box to enter the rogue duty-cycle.
5. Click **Apply** .

The wireless controller updates 802.11 channel assignments according to your configured parameters.

Configure 802.11 channel assignment parameters (CLI)

Configure Advanced 802.11 Channel Assignment Parameters using commands.

Configure DCA and related parameters on 802.11 radios.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure CleanAir event-driven RRM parameters.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz} rrm channel cleanair-event sensitivity
 {high | low | medium}
```

The types of sensitivity are:

- **High** : Specifies the most sensitivity to non-Wi-Fi interference as indicated by the air quality (AQ) value.
- **Low** : Specifies the least sensitivity to non-Wi-Fi interference as indicated by the AQ value.
- **Medium** : Specifies medium sensitivity to non-Wi-Fi interference as indicated by the AQ value.

3. Configure 802.11 6GHz DCA algorithm parameters.

Example

```
Device(config)# ap dot11 6ghz rrm channel dca {anchor-time <0-23> | global
auto | interval <0-24> sensitivity {high | low | medium}}
```

The DCA algorithm parameters include:

- **anchor-time**: Configures the anchor time for the DCA. The range is from 0 to 23 hours.
- **global**: Configures the DCA mode for all 802.11 Cisco APs.
  - **auto**: Enables auto-RF.
- **interval**: Configures the DCA interval value. The values are 1, 2, 3, 4, 6, 8, 12 and 24 hours, and the default value 0 denotes 10 minutes.
- **sensitivity**: Configures the DCA sensitivity level to changes in the environment.
  - **high**: Specifies the most sensitivity.
  - **low**: Specifies the least sensitivity.
  - **medium**: Specifies medium sensitivity.

4. Configure the DCA channel bandwidth for all 802.11 radios in the 5-GHz band.

   Example

   ```
   Device(config)# ap dot11 5ghz rrm channel dca chan-width {20 | 40 | 80 | best}
   ```

   The channel bandwidth can be set to 20 MHz, 40 MHz, or 80 MHz, . The default value for channel bandwidth is 20 MHz (80 MHz is the default value for Best). Set the channel bandwidth to Best before configuring the constraints.

5. Configure the maximum channel bandwidth that can be assigned to a channel.

   Example

   ```
   Device(config)# ap dot11 5ghz rrm channel dca chan-width width-max {WIDTH_20MHz
    | WIDTH_40MHz | WIDTH_80MHz |WIDTH_MAX}
   ```

   WIDTH_80MHz assigns the channel bandwidth to 20 MHz, 40 MHz, or 80 MHz but not greater than that.

6. Configure the maximum channel bandwidth that can be assigned to a channel.

   Example

   ```
   Device(config)# ap dot11 6ghz rrm channel
   dca chan-width width-max {WIDTH_200MHz | WIDTH_40MHz | WIDTH_80MHz | WIDTH_MAX}
   ```

   WIDTH_80MHz assigns the channel bandwidth to 20 MHz, 40 MHz, or 80 MHz but not greater than that.

The 802.11 channel assignment parameters are configured.

What to do next

Configure the advanced channel assignment parameters.

Configure the advanced channel assignment parameters (CLI)

Procedure

1. Configure the persistent non-Wi-Fi device avoidance in the 802.11 channel assignment.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm channel device
   ```

2. Configure the foreign AP 802.11 interference avoidance in the channel assignment.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm channel foreign
   ```

3. Configure the Cisco AP 802.11 load avoidance in the channel assignment.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm channel load
   ```

4. Configure noise avoidance in 802.11 channel assignment.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm channel noise
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   You can also press **Ctrl-Z** to exit global configuration mode.

The 802.11 advanced channel assignment parameters are configured.

```
Device(config)# ap dot11 {24ghz | 5ghz} rrm channel noise
  Device(config)# end
```

Configure 802.11 coverage hole detection (GUI)

Configure 802.11 Coverage Hole Detection using GUI.

Enable 802.11 coverage hole detection to optimize wireless radio coverage and identify areas with inadequate connectivity.

Use this task when you want to detect and troubleshoot Wi-Fi coverage gaps on 6 GHz, 5 GHz, or 2.4 GHz radio bands in your wireless network.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM** to configure Radio Resource Management parameters for 802.11ax (6 GHz), 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios.
2. On the **Radio Resource Management** page, click the **Coverage** tab and complete these steps:
   a) To enable coverage hole detection, check the **Enable Coverage Hole Detection** check box.
   b) In the **Data Packet Count** field, enter the number of data packets.
   c) In the **Data Packet Percentage** field, enter the percentage of data packets.
   d) In the **Data RSSI Threshold** field, enter the actual value in dBm. The range is from -60 dBm to -90 dBm. The default value is -80 dBm.
   e) In the **Voice Packet Count** field, enter the number of voice data packets.
   f) In the **Voice Packet Percentage** field, enter the percentage of voice data packets.
   g) In the **Voice RSSI Threshold** field, enter the actual value in dBm. The range is from -60 dBm to -90 dBm. The default value is -80 dBm.
   h) In the **Minimum Failed Client per AP** field, enter the minimum number of clients on an AP with a signal-to-noise ratio (SNR) below the coverage threshold. The range is from 1 to 75, and the default value is 3.
   i) In the **Percent Coverage Exception Level per AP** field, enter the maximum desired percentage of clients on an access point's radio operating below the desired coverage threshold. The range is from 0 to 100%, and the default value is 25%.
3. Click **Apply**.

Your configuration is saved and the system begins monitoring for coverage holes based on the specified parameters.

Configure 802.11 coverage hole detection (CLI)

Configure 802.11 Coverage Hole Detection using commands.

Set up coverage hole detection for your wireless network.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the 802.11 6 GHz coverage hole detection for data packets.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm coverage data
   {fail-percentage | packet-count} value
   ```

   The attributes for the data packets are:

   - **fail-percentage**: Configures the 802.11 6-GHz coverage failure rate threshold for uplink data packets as a percentage that ranges from 1 to 100 percent.
   - **packet-count**: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink data packets that ranges from 1 to 255.

3. Configure the 802.11 AP coverage exception level as a percentage that ranges from 0 to 100 percent.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz} rrm coverage exception global
exception-level
```

4. Set the minimum exception level for AP clients.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm coverage level global cli_min
   exception level
   ```

   The value range is from 1 to 75 clients.

5. Configure the 802.11 6 GHz coverage hole detection for voice packets.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm coverage voice
   {fail-percentage | packet-count} value
   ```

   The attributes for voice packets are:

   - **fail-percentage**: Configures the 802.11 6-GHz coverage failure rate threshold for uplink voice packets as a percentage that ranges from 1 to 100 percent.
   - **packet-count**: Configures the 802.11 6-GHz coverage minimum failure count threshold for uplink voice packets that ranges from 1 to 255.

6. Return to privileged EXEC mode to complete configuration.

   Example

   ```
   Device(config)# end
   ```

   ress **Ctrl-Z** to exit global configuration mode.

After you configure coverage hole detection thresholds, the wireless APs monitor your network and send alerts about coverage gaps.

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm coverage data fail-percentage 60
Device(config)# ap dot11 6ghz rrm coverage data fail-percentage 60
Device(config)# ap dot11 24ghz rrm coverage exception global 50
Device(config)# ap dot11 24ghz rrm coverage level global 10
Device(config)# ap dot11 24ghz rrm coverage voice packet-count 10
Device(config)# ap dot11 6ghz rrm coverage voice packet-count 10
Device(config)# end
```

Configure 802.11 event logging (CLI)

Configure 802.11 Event Logging using commands.

Enable and customize event logging for 802.11 wireless network parameters.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure event-logging for various parameters.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm logging {channel | coverage
    | foreign | load | noise | performance | txpower}
   ```

   The event-logging parameters include:

   - **channel**: Configures the 802.11 channel change logging mode.
   - **coverage**: Configures the 802.11 coverage profile logging mode.
   - **foreign**: Configures the 802.11 foreign interference profile logging mode.
   - **load**: Configures the 802.11 load profile logging mode.
   - **noise**: Configures the 802.11 noise profile logging mode.
   - **performance**: Configures the 802.11 performance profile logging mode.
   - **txpower**: Configures the 802.11 transmit power change logging mode.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   You can also press **Ctrl-Z** to exit global configuration mode.

You have enabled 802.11 event logging for the specified parameters.

```
Device# configure terminal

Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm logging {channel | coverage
 | foreign | load | noise | performance | txpower}
Device(config)# end
```

Configure 802.11 statistics monitoring (GUI)

Configure 802.11 Statistics Monitoring using GUI.

Enable and customize radio statistics monitoring intervals for APs.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM** to configure Radio Resource Management parameters for 802.11ax (6 GHz), 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios.
2. In the **Monitor Intervals (60 to 3600 secs)** section:
   a) To configure the 802.11 noise measurement interval (channel scan interval), set the **AP Noise Interval**. The valid range is from 60 to 3,600 seconds.
   b) To configure the 802.11 signal measurement interval (neighbor packet frequency), set the **AP Signal Strength Interval**. The valid range is from 60 to 3,600 seconds.
   c) To configure the 802.11 coverage measurement interval, set the **AP Coverage Interval**. The valid range is from 60 to 3,600 seconds.
   d) To configure the 802.11 load measurement, set the **AP Load Interval**. The valid range is from 60 to 3,600 seconds.
3. Click **Apply**.

802.11 statistics monitoring intervals are applied to the selected radios.

Configure 802.11 statistics monitoring (CLI)

Configure 802.11 Statistics Monitoring using commands.

Enable or customize the monitoring of 802.11 statistics on wireless APs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the 802.11 monitoring channel-list for parameters such as noise/interference/rogue.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor channel-list {all
    | country | dca}
   ```

   The channel list parameters include:

   - **all**: Monitors all channels.
   - **country**: Monitor channels used in configured country code.
   - **dca**: Monitor channels used by dynamic channel assignment.

3. Configure the 802.11 coverage measurement interval in seconds, which ranges from 60 to 3,600.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor coverage interval
   ```

4. Configure the 802.11 load measurement interval in seconds, which ranges from 60 to 3,600.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor load interval
```

5. Configure the 802.11 noise measurement interval (channel scan interval) in seconds, which ranges from 60 to 3,600.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor noise interval
```

6. Configure the 802.11 signal measurement interval (neighbor packet frequency) in seconds, which ranges from 60 to 3,600.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor signal interval
```

7. Configure the 802.11 RRM Neighbor Discovery RSSI normalization.

Example

```
Device(config)#ap dot11 {24ghz | 5ghz | 6ghz} rrm monitor rssi-normalization
```

The system applies your 802.11 statistics monitoring settings to the APs.

```
Device# configure terminal
Device(config)# ap dot11 6ghz rrm monitor channel-list all
Device(config)# ap dot11 6ghz rrm monitor coverage 600
Device(config)# ap dot11 6ghz rrm monitor load 180
Device(config)# ap dot11 6ghz rrm monitor noise 360
Device(config)# ap dot11 6ghz rrm monitor signal 480
Device(config)# ap dot11 6ghz rrm monitor rssi-normalization
```

Configure the 802.11 performance profile (GUI)

Configure the 802.11 Performance Profile using GUI.

Define radio frequency parameters to optimize AP performance in 802.11 networks.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join** page, click the name of the profile or click **Add** to create a new one.
3. In the **Add/Edit RF Profile** window, click the **RRM** tab.
4. In the **General** tab that is displayed, enter the following parameters:
   a) In the **Interference (%)** field, enter the threshold value for 802.11 foreign interference, which ranges from 0 to 100 percent.
   b) In the **Clients** field, enter the threshold value for 802.11 Cisco AP clients, which ranges from 1 to 75 clients.
   c) In the **Noise (dBm)** field, enter the threshold value for 802.11 foreign noise, which ranges from -127 dBm to 0 dBm.

d) In the **Utilization(%)** field, enter the threshold value for 802.11 RF utilization, which ranges from 0 to 100 percent.

5. Click **Update & Apply to Device**.

The 802.11 performance profile is applied to the selected APs.

Configure the 802.11 performance profile (CLI)

This topic provides information on configuring performance profile.

Configure threshold values for 802.11 performance parameters, including clients, interference, noise, throughput, and RF utilization, on Cisco APs.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the threshold value for 802.11 Cisco AP clients, which ranges from 1 to 75 clients.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm profile clients cli_threshold_value
   ```

3. Set the threshold value for 802.11 foreign interference, which ranges from 0 to 100 percent.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm profile foreign int_threshold_value
   ```

4. Set the threshold value for 802.11 foreign noise, which ranges from -127 to 0 dBm.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm profile noise
   for_noise_threshold_value
   ```

5. Enable performance profiles.

   Example

   ```
   Device(config)# ap dot11 6ghz rrm profile customize
   ```

6. Set the threshold value for 802.11 Cisco AP throughput, which ranges from 1000 to 10000000 bytes per second.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm profile throughput
   throughput_threshold_value
   ```

7. Set the threshold value for 802.11 RF utilization, which ranges from 0 to 100 percent.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} rrm profile utilization
   rf_util_threshold_value
   ```

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The AP's performance profile is updated with your specified threshold values, enabling automated monitoring and adjustment of wireless network conditions according to configured criteria.

```
Device# configure terminal
Device(config)# ap dot11 24ghz rrm profile clients 20
Device(config)# ap dot11 24ghz rrm profile foreign 50
Device(config)# ap dot11 24ghz rrm profile noise -65

Device(config)# ap dot11 6ghz rrm profile customize
Device(config)# ap dot11 24ghz rrm profile throughput 10000
Device(config)# ap dot11 24ghz rrm profile utilization 75
Device(config)# end
```

Configure advanced 802.11 RRM

-

Enable channel assignment (GUI)

Enable Channel Assignment using GUI.

To optimize wireless performance, assign device radio channels either automatically or manually.

Procedure

---

1. Choose **Configuration** > **Radio Configurations** > **RRM**.
2. In the **RRM** page, click the relevant band's tab: either **6 GHz Band**, **5 GHz Band** or **2.4 GHz Band**.
3. Click the **DCA** tab.
4. In the **Dynamic Channel Assignment Algorithm** section, choose the appropriate **Channel Assignment Mode**:
   - **Automatic**: Sets the channel assignment to automatic.
   - **Freeze**: Locks the channel assignment. Click **Invoke Channel Update Once** to refresh the assigned channels.
5. Click **Apply**.

Dynamic channel assignment is enabled based on your selection. You can configure radios to use automatic or manual channel allocation.

Enable channel assignment (CLI)

Enable Channel Assignment using commands.

To optimize radio resource allocation, assign wireless channels to 802.11 APs.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enable the 802.11 channel selection update for each AP.

   Example

   ```
   Device# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel-update
   ```

   Note

   After enabling the feature, the DCA algorithm assigns a token for channel assignment.

The system applies the DCA algorithm to update wireless channel assignments on all APs for the specified frequency.

```
Device# enable
Device# ap dot11 24ghz rrm channel-update
```

Restart DCA operation

Restart DCA Operation using commands.

To restore optimal channel allocation for wireless radios, restart the Dynamic Channel Assignment (DCA).

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Restart the DCA cycle for the 802.11 radio.

Example

```
Device# ap dot11 {24ghz | 5ghz  | 6ghz} rrm dca restart
```

The DCA process restarts on the wireless device.

```
Device# enable
Device# ap dot11 24ghz rrm dca restart
```

Update power assignment parameters (GUI)

Update Power Assignment Parameters using GUI.

Change the transmit power assignment settings for your AP to optimize wireless coverage.

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **Access Points** page, click the name of the AP from the 5 GHz or 2.4 GHz list.
3. In the **Edit Radios** > **Configure** > **Tx Power Level Assignment** section, select **Custom** from the **Assignment Method** group-down list.
4. Select the value for **Transmit Power** from the drop-down list.
5. Click **Update & Apply to Device**.

The system applies the updated transmit power parameters to your selected AP.

Update power assignment parameters (CLI)

Update Power Assignment Parameters using commands.

Adjust the wireless transmit power settings for APs to optimize coverage and performance.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Update the 802.11 6 GHz transmit power for every AP.

   Example

   ```
   Device# ap dot11 {24ghz | 5ghz | 6ghz} rrm txpower update
   ```

The system updates the transmit power configuration for the specified APs.

```
Device# enable
Device# ap dot11 24ghz rrm txpower update
Device# ap dot11 6ghz rrm txpower update
```

Monitor RRM parameters and RF group status

Monitor Radio Resource Management (RRM) parameters and RF group status using **show** commands to optimize wireless network performance.

Monitor RRM parameters

Monitor RRM Parameters using commands.

Provide a quick reference to the commands used for monitoring Radio Resource Management (RRM) parameters, enabling users to efficiently assess and troubleshoot wireless network performance.

Table 63: Commands for monitoring Radio Resource Management

Commands	Description
show ap dot11 24ghz channel	Displays the configuration and statistics of the 802.11b monitoring.
show ap dot11 24ghz coverage	Displays the configuration and statistics of the 802.11b coverage.
show ap dot11 24ghz group	Displays the configuration and statistics of the 802.11b grouping.
show ap dot11 24ghz logging	Displays the configuration and statistics of the 802.11b event logging.
show ap dot11 24ghz monitor	Displays the configuration and statistics of the 802.11b monitoring. nnn
show ap dot11 24ghz profile	Displays 802.11b profiling information for all APs.
show ap dot11 24ghz summary	Displays the configuration and statistics of the 802.11a APs.
show ap dot11 24ghz txpower	Displays the configuration and statistics of the 802.11b transmit power control.
show ap dot11 5ghz channel	Displays the configuration and statistics of the 802.11a channel assignment.
show ap dot11 5ghz coverage	Displays the configuration and statistics of the 802.11a coverage.
show ap dot11 5ghz group	Displays the configuration and statistics of the 802.11a grouping.
show ap dot11 5ghz logging	Displays the configuration and statistics of the 802.11a event logging.
show ap dot11 5ghz monitor	Displays the configuration and statistics of the 802.11a monitoring.

Commands	Description
show ap dot11 5ghz profile	Displays 802.11a profiling information for all APs.
show ap dot11 5ghz summary	Displays the configuration and statistics of the 802.11a APs.
show ap dot11 5ghz txpower	Displays the configuration and statistics of the 802.11a transmit power control.

Verify RF group status

Verify RF Group Status using commands.

This section describes the new commands for RF group status.

These commands are used to verify RF group status on the .

This table lists the commands for verifying aggressive load balancing.

Table 64: Aggressive load balancing verification commands

Command	Purpose
show ap dot11 5ghz group	Displays the controller name that is the group leader for the 802.11a RF network.
show ap dot11 24ghz group	Displays the controller name that is the group leader for the 802.11b/g RF network.
show ap dot11 6ghz group	Displays the controller name that is the group leader for the 802.11 6-GHz RF network.

To display the controller as a remote member and part of the AI Enhanced RRM, use this command:

```
Device# show ap dot11 24ghz group

Radio RF Grouping

RF Group Name : Open-RRM
RF Protocol Version(MIN) : 100(30)
RF Packet Header Version : 2
802.11b Group Mode : AUTO
802.11b Group Role : Remote-Member
802.11b Group Update Interval : 600 seconds
802.11b Group Leader : 172.19.30.39 (172.19.30.39)
Secure-RRM : Disabled

RF Group Members

Controller name Controller IP Controller IPv6 DTLS status
------------------------------------------------------------------------------------------
evwlc-188         192.0.2.188     N/A
```

Event-Driven Radio Resource Management

ED-RRM details.

A Event-Driven Radio Resource Management (ED-RRM) feature is a radio frequency management solution that

- continuously monitors air quality metrics
- automatically triggers channel changes when interference exceeds a set threshold, and
- blocks affected channels for a specified duration to prevent immediate reselection.

Spontaneous interference is interference that appears suddenly on a network, perhaps jamming a channel or a range of channels completely. The Cisco CleanAir spectrum event-driven RRM feature allows you to set a threshold for air quality (AQ) that, if exceeded, triggers an immediate channel change for the affected AP. Once a channel change occurs due to event-driven RRM, the channel is blocked list for three hours to avoid selection.

Most RF management systems can avoid interference, but this information takes time to propagate through the system. Cisco CleanAir relies on AQ measurements to continuously evaluate the spectrum and can trigger a move within 30 seconds. For example, if an AP detects interference from a video camera, it can recover by changing channels within 30 seconds of the camera becoming active.

Configure ED-RRM on the controller (CLI)

Configure ED-RRM using commands.

Configure Event-Driven Radio Resource Management (ED-RRM) on the controller using CLI commands.

Trigger spectrum event-driven RRM to run when a Cisco CleanAir-enabled AP detects a significant level of interference by entering these commands.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure CleanAir driven RRM parameters for the 802.11 APs.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel cleanair-event
   ```

3. Configure CleanAir driven RRM sensitivity for the 802.11 APs.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel cleanair-event
   sensitivity {low | medium | high | custom}
   ```

   Default selection is Medium.

4. Trigger the ED-RRM event at the set threshold value.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel cleanair-event
custom-threshold custom-threshold-value
```

The custom threshold range is from 1 to 99.

5. Enable rogue contribution.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel cleanair-event
rogue-contribution
```

6. Configure threshold value for rogue contribution.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm channel cleanair-event
rogue-contribution duty-cycle thresholdvalue
```

The range is from 1 to 99, with 80 as the default.

7. Save your changes.

Example

```
Device# write memory
```

8. Optional: Verify the CleanAir configuration for the 802.11a/n/ac or 802.11b/g/n network.

Example

```
Device# show ap dot11 {24ghz | 5ghz | 6ghz}cleanair config
```

The output is displayed.

The Event-Driven Radio Resource Management (ED-RRM) on the controller is configured.

Rogue detection - rogue channel width

Rogue detection - rogue channel width details.

A rogue detection configuration is a security measure that

- allows specifying channel width and band for detecting unauthorized APs, and
- filters rogue APs based on matching channel width criteria and band.

The **condition chan-width** command is introduced in Cisco IOS XE Dublin 17.12.1 allows you to set the minimum or maximum channel width for rogue detection.

Configure rogue channel width (CLI)

Configure rogue channel width using commands.

Complete this task to configure rogue channel width.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create or enable a rule.

   Example

   ```
   Device(config)# wireless wps rogue rule rule-name priority priority
   ```

3. Configure channel width and band for rogue detection.

   Example

   ```
   Device(config-rule)# condition chan-width {160MHz | 20MHz | 40MHz | 80MHz}
   band {24ghz | 5ghz | 6ghz}
   ```

   If the classification is **Friendly**, this is the minimum channel width.

   If the classification is **Custom**, **Malicious**, or **Delete**, this is the maximum channel width.

4. Use Step 4, 5, 6, or 7.

   > **Note**
   >
   > Use only one of the Steps: 4, 5, 6, or 7 as required to classify rogue devices. Do not use all of them.

5. Optional: Classify devices matching this rule as friendly.

   Example

   ```
   Device(config-rule)# classify friendly state {alert | external | internal}
   ```

   The options are:

   - **alert**: Sets the malicious rogue access point to alert mode.
   - **external**: Acknowledges the presence of a rogue access point.
   - **internal**: Trusts a foreign access point.

6. Optional: Classify devices matching this rule as malicious.

   Example

   ```
   Device(config-rule)# classify malicious state {alert | contained}
   ```

   The options are:

   - **alert**: Sets the malicious rogue AP to alert mode.

- **contained**: Contains the rogue AP.

7. Optional: Classify devices matching this rule as custom.

   Example

   ```
   Device(config-rule)# classify custom severity-score severity-score [name name]
    state {alert | contained}
   ```

   Here the options are:

   - *severity-score* : Custom classification severity score. The range is from 1 to 100.
   - **name**: Defines the name for custom classification.
   - *name* : Specifies the custom classification name.
   - **state**: Defines the final state if rule is matched.
   - **alert**: Sets the rogue AP to alert mode.
   - **contained**: Contains the rogue AP.

8. Ignore the devices matching this rule.

   Example

   ```
   Device(config-rule)# classify delete
   ```

9. Return to privileged EXEC mode.

   Example

   ```
   Device(config-rule)# end
   ```

The rogue channel width is configured.

```
Device# configure terminal
                Device(config)# wireless wps rogue rule 1 priority 1
                Device(config-rule)# condition chan-width 20MHz band 5ghz
                Device(config-rule)# classify friendly state internal
                Device(config-rule)# classify malicious state alert
                Device(config-rule)# classify custom severity-score 12 name
rule1 state alert
                Device(config-rule)# classify delete
                Device(config-rule)# end
```

Configure rogue classification rules (GUI)

Configure rogue classification rules using GUI.

Complete this task to configure rogue classification rules.

Procedure

1. Choose **Configuration** > **Security** > **Wireless Protection Policies** > **Rogue AP Rules** to open the **Rogue Rules** window.

   Rules that have already been created are listed in priority order. The name, type, status, state, match, and hit count of each rule is provided.

   > **Note**
   >
   > To delete a rule, select the rule and click **Delete**.

2. Create a new rule with these steps:
   a) Click **Add**.
   b) In the **Add Rogue AP Rule** window, enter a name for the new rule, in the **Rule Name** field. Ensure that the name does not contain any spaces.
   c) From the **Rule Type** drop-down list, choose one of these options to classify rogue APs matching this rule:
      - **Friendly**
      - **Malicious**
      - **Unclassified**
      - **Custom**

   d) From the **State** drop-down list, configure the state of the rogue AP. This is the state when the rule matches the conditions for the rogue APs.
      - **Alert**: A trap is generated when an ad hoc rogue is detected.
      - **Internal**: A foreign ad hoc rogue is trusted.
      - **External**: The presence of an ad hoc rogue is acknowledged.
      - **Contain**: The ad hoc rogue is contained.
      - **Delete**: The ad hoc rogue is removed.

      > **Note**
      >
      > The **State** field is not displayed if you select **Unclassified** as the **Rule Type**.

   e) If you chose the **Rule Type** as **Custom**, enter the **Severity Score** and the **Custom Name**.
   f) Click **Apply to Device** to add this rule to the list of existing rules, or click **Cancel** to discard this new rule.
3. Optional: Edit a rule using these steps:
   a) Click the name of the rule that you want to edit.
   b) In the **Edit Rogue AP Rule** page that is displayed, from the **Type** drop-down list, choose one of these options to classify rogue APs matching this rule:
      - **Friendly**

- **Malicious**
- **Custom**

c) Configure the notification from the **Notify** drop-down list to **All**, **Global**, **Local**, or **None** after the rule is matched.
d) Configure the state of the rogue AP from the **State** drop-down list after the rule is matched.
e) From the **Match Operation** field, choose one of these options:

- **Match All**: The detected rogue AP must meet all of the conditions specified by the rule for the rule to be matched and the rogue AP to adopt the classification type of the rule.
- **Match Any**: The detected rogue AP must meet any of the conditions specified by the rule for the rule to be matched and the rogue AP to adopt the classification type of the rule. This is the default value.

f) To enable this rule, check the **Enable Rule** check box. The default is unchecked.
g) If you chose the **Rule Type** as **Custom**, enter the **Severity Score** and the **Classification Name**.
h) From the **Add Condition** drop-down list, choose one or more of the conditions that the rogue AP must meet:

- **None**: No condition is set for rogue AP detection.
- **client-count**: Condition requires that a minimum number of clients be associated to the rogue AP. For example, if the number of clients associated to the rogue AP is greater than or equal to the configured value, then the AP can be classified as malicious. If you choose this option, enter the minimum number of clients to be associated with the rogue AP in the **Minimum Number of Rogue Clients** field. The valid range is 1 to 10 (inclusive), and the default value is 0.
- **duration**: Condition requires that the rogue AP be detected for a minimum period of time. If you choose this option, enter a value for the minimum detection period in the **Time Duration** field. The valid range is 0 to 86400 seconds (inclusive), and the default value is 0 seconds.
- **encryption**: Condition requires that the advertised WLAN have specified encryption. Requires that the rogue AP's advertised WLAN does not have encryption enabled. If a rogue AP has encryption disabled, it is likely that more clients will try to associate with it. No further configuration is required for this option.
- **infrastructure**: Condition requires that the rogue AP's SSID (the SSID configured for the WLAN) be known to the controller. Select the **Manage SSID** check box to enable this configuration.
- **rssi**: Condition requires that the rogue AP have a minimum received signal strength indication (RSSI) value. For example, if the rogue AP has an RSSI that is greater than the configured value, then the AP could be classified as malicious. If you choose this option, enter the minimum RSSI value in the **Maximum RSSI** field. The valid range is 0 to -128 dBm (inclusive).
- **channel-width**: Condition requires that the rogue AP use the specified radio spectrum channel width for the specified radio band, as defined. The valid channel widths are 20, 40, 80, and 160MHz.
  - For APs to be classified as **Malicious**, **Custom** or **Delete**, it must match the value (equal or more) set in the **Minimum Channel Width** drop-down list.
  - For APs to be classified as **Friendly**, it must match the value (equal or less) set using an option from the **Maximum Channel Width** drop-down list.
- **ssid**: Condition requires that the rogue AP have a specific user-configured SSID. If you choose this option, enter the SSID in the **User Configured SSID** text field, and click **+** to add the SSID.
- **substring-ssid**: Condition requires that the rogue AP have a substring of the specific user-configured SSID. The controller searches the substring in the same occurrence pattern and returns a match if the substring is found in the SSID string.

4. Click **Apply to Device** to save the configuration.

5. Click **OK**.

The rogue classification rules are configured.

Verify rogue channel width

Verify rogue channel width details.

To view channel width and band information of a classification rule, use these commands.

> **Note**
>
> When the same BSSID is beaconing on multiple bands (2.4 GHz, 5 GHz, 6 GHz), the **show wireless wps rogue ap summary** command output displays information for the band with the highest RSSI.

```
Device# show wireless wps rogue rule detailed 1

48 Coverage Hole Detection

Topics:

- Coverage hole detection and correction

Coverage hole detection and correction

Details the coverage hole detection and correction algorithm, including alerting administrators to insufficient wireless coverage, discriminating between correctable and uncorrectable holes, and adjusting AP transmit power to mitigate coverage issues.

A coverage hole detection and correction algorithm is a wireless LAN management mechanism that

- identifies areas with insufficient radio coverage for reliable performance
- alerts administrators when access points fail to provide adequate coverage, and
- adjusts AP transmit power to mitigate correctable coverage holes.

If clients on a lightweight AP are detected at threshold levels such as RSSI, failed client count, percentage of failed packets, and number of failed packets that are lower than those specified in the RRM configuration, the AP sends a "coverage hole" alert to the device. The alert indicates that clients cannot connect to a usable AP because of poor signal coverage.

The device discriminates between coverage holes that can and cannot be corrected. For coverage holes that can be corrected, the device mitigates the coverage hole by increasing the transmit power level for that specific AP.

The device does not mitigate coverage holes caused by clients that are unable to increase their transmit power or are statically set to a power level. Increasing downstream transmit power could increase interference in the network.

Configure coverage hole detection (GUI)

Configure coverage hole detection using the GUI.

Enable Coverage hole detection (CHD) to configure client accounting using the GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM**.
2. Configure the Radio Resource Management parameters for 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios, and flexible radio assignment parameters.
3. Check the **Enable Coverage Hole Detection** check box to activate the feature.

CHD is enabled. The system identifies and reports wireless coverage gaps.

Configure coverage hole detection (CLI)

Configure coverage hole detection using commands.

CHD is based on upstream RSSI metrics observed by the AP. Enable CHD on your wireless device using CLI commands.

> **Note**
>
> To revert back radios from 5-GHz to 24-GHz for CHD, ensure that the 5-GHz radio is UP and client network preference value is other than the default.

Before you begin

Disable the 802.11 network before applying the configuration.

Procedure

1. Configure the 802.11 coverage level for data packets.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm coverage
   ```

   The options are:

   - **24ghz**: Configure 802.11b parameters.
   - **5ghz**: Configure 802.11a parameters.
   - **6ghz**: Configure 802.11 6 GHz parameters.

2. Configure the 802.11 coverage level for data packets.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rrm coverage data
   {fail-percentage | packet-count | rssi-threshold} 60
   ```

   The options are:

   - **fail-percentage**: Configures 802.11b coverage failure rate threshold for uplink data packets.
   - **packet-count**: Configures 802.11b coverage minimum failure count threshold for uplinkvoice packets.
   - **rssi-threshold**: Configures 802.11b minimum receive coverage level for voice packets.

3. Configure the 802.11 6-GHz coverage hole detection for data packets.

   Example

   ```
   Device(config)# ap dot11 6ghz rrm coverage data {fail-percentage |
   packet-count} 60
   ```

   The options are:

   - **fail-percentage**: Configures 802.11b coverage failure rate threshold for uplink data packets.
   - **packet-count**: Configures 802.11b coverage minimum failure count threshold for uplinkvoice packets.

4. Configure the 802.11 Cisco AP coverage exception level as a percentage that ranges from zero to 100%.

Example

```
Device(config)# ap dot11 24ghz rrm coverage exception global 50
```

5. Configure the 802.11 Cisco AP client minimum exception level that ranges from one to 75 clients.

   Example

   ```
   Device(config)# ap dot11 24ghz rrm coverage level global 10
   ```

6. Configure the 802.11 coverage hole detection for voice packets.

   Example

   ```
   Device(config)# ap dot11 24ghz rrm coverage voice {fail-percentage |
   packet-count | rssi-threshold} 10
   ```

   The options are:

   - **fail-percentage**: Configures 802.11b coverage failure rate threshold for uplink data packets.
   - **packet-count**: Configures 802.11b coverage minimum failure count threshold for uplinkvoice packets.
   - **rssi-threshold**: Configures 802.11b minimum receive coverage level for voice packets.

7. Configure the 802.11 6-GHz coverage hole detection for voice packets.

   Example

   ```
   Device(config)# ap dot11 6ghz rrm coverage voice {fail-percentage |
   packet-count} 10
   ```

   The options are:

   - **fail-percentage**: Configures 802.11b coverage failure rate threshold for uplink data packets.
   - **packet-count**: Configures 802.11b coverage minimum failure count threshold for uplinkvoice packets.

8. Save the configuration and return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

9. Verify the CHD details.

   Example

   ```
   Device# show ap dot11 {24ghz | 5ghz | 6ghz} coverage
   ```

   This displays CHD status and statistics.

> **Note**
>
> If both the number and percentage of failed packets exceed the values entered in the **packet-count** and **fail-percentage** commands for a five-second period, the client enters a pre-alarm condition. The controller uses this information to distinguish between real and false coverage holes. False positives typically result from poor roaming logic implemented on most clients.
>
> A coverage hole is detected if both the number and percentage of failed clients meet or exceed the values entered in the coverage level global and coverage exception global commands over a 90-second period. The controller determines if the coverage hole can be corrected and, if appropriate, increases the transmit power level for that specific AP.

Configure CHD for RF tag profile (GUI)

Configure CHD for RF tag profile using GUI.

Enable and configure CHD parameters for an RF tag profile using the GUI to ensure optimal wireless coverage.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM**.
2. On the **Coverage** tab, select the **Enable Coverage Hole Detection** check box.
3. In the **Data RSSI Threshold** field, enter the actual value in dBm. The valid value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
4. In the **Voice RSSI Threshold** field, enter the actual value in dBm. The valid value ranges from -60 dBm to -90 dBm; the default value is -80 dBm.
5. In the **Minimum Failed Client per AP** field, enter the minimum number of clients on an AP with a signal-to-noise ratio (SNR) below the coverage threshold. The valid value ranges from one to 75 and the default value is three.
6. In the **Percent Coverage Exception Level per AP** field, enter the maximum desired percentage of clients on an AP's radio operating below the desired coverage threshold and click Apply. The valid value ranges from zero to 100% and the default value is 25%.
7. In the **Voice Packet Count** and **Voice Packet Percentage** fields, enter the number and percentage of voice data packets.
8. In the **Data Packet Count** and **Data Packet Percentage** fields, enter the number and percentage of data packets.
9. Click **Apply**.

Configuring CHD for RF profile (CLI)

Configure CHD for RF profile using commands.

Enable CHD for a specified RF profile on your wireless device using CLI commands.

Before you begin
Ensure that the RF profile is already created.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the 802.11 coverage hole detection for data packets.

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile alpha-rfprofile-24ghz
   ```

3. Configure the minimum RSSI value for data packets received by the AP. The valid values range is from -90 to -60 in dBm.

   Example

   ```
   Device(config-rf-profile)# coverage data rssi threshold -80
   ```

4. Save the configuration and return to privileged EXEC mode.

   Example

   ```
   Device(config-rf-profile)# end
   ```

5. Verify the summary of the available RF profiles.

   Example

   ```
   Device# show ap dot11 24ghz rf-profile summary
   ```

49 Optimized Roaming

Topics:

- Optimized roaming

The Cisco Catalyst 9800 Series Wireless Controller Software Configuration Guide for Smart Roaming explains how to optimize client roaming by disassociating clients with low RSSI or data rates to prevent sticky clients and improve connection stability. It details configuration steps for enabling optimized roaming via GUI or CLI, including setting data rate thresholds and hysteresis values to enhance wireless client mobility and network performance.

Optimized roaming

Introduces optimized roaming technology, outlining its key functions and behavior, and describes deployment restrictions and use cases. Provides instructions for configuring optimized roaming using the GUI and CLI, covering both legacy and new workflows.

Optimized roaming is a Wi-Fi network feature that

- resolves the problem of sticky clients that remain associated to access points that are far away and outbound clients that attempt to connect to a Wi-Fi network without having a stable connection
- disassociates clients based on the RSSI of the client data packets and data rate when the RSSI alarm condition is met and the current data rate of the client is lower than the optimized roaming data rate threshold, and
- prevents client association when the client's RSSI is low by checking the RSSI of the incoming client against the RSSI threshold.

Additional optimized roaming information

You can disable the data rate option so that only RSSI is used for disassociating clients.

This feature checks the RSSI of the incoming client against the RSSI threshold, which is configured in the same place as the Coverage Hole Detection. This check prevents the clients from connecting to a Wi-Fi network unless the client has a viable connection. In many scenarios, even though clients can hear beacons and connect to a Wi-Fi network, the signal might not be strong enough to support a stable connection.

You can also configure the client coverage reporting interval for a radio by using optimized roaming. The client coverage statistics include data packet RSSIs, Coverage Hole Detection and Mitigation (CHDM) pre-alarm failures, retransmission requests, and current data rates.

Optimized roaming is useful in these scenarios:

- Addresses the sticky client challenge by proactively disconnecting clients.
- Actively monitors data RSSI packets.
- Disassociates client when the RSSI is lower than the set threshold.

Restrictions for optimized roaming

Lists optimized roaming restrictions.

Lists the restrictions that apply when using the optimized roaming feature on Cisco wireless controllers.

- When basic service set (*BSS*) transition is sent to 802.11v-capable clients, and if the clients are not transitioned to other BSS before the disconnect timer expires, the corresponding client is disconnected forcefully. BSS transition is enabled by default for 802.11v-capable clients.
- The Cisco Catalyst 9800 controller increments the 80211v smart roam failed counter while disconnecting the client due to optimized roaming.
- We recommend that you do not use the optimized roaming feature with RSSI low check.

Configure optimized roaming (GUI)

Configure Optimized Roaming using GUI to improve wireless client connectivity by managing disassociation thresholds and data rates.

Optimized roaming helps maintain optimal wireless client connectivity by managing when clients are disassociated based on RSSI and data rate thresholds.

Procedure

1. Choose **Configuration** > **Wireless** > **Advanced**.
2. Click the **Optimized Roaming** tab.
3. Check the **Optimized Roaming Mode** check box in the **6 GHz Band**, **5 GHz Band**, or, **2.4 GHz Band** sections to enable the feature.

   Note

   Modifying the default settings for the **Optimized Roaming data rate** and CHDM RSSI configurations could result in unintended client connectivity problems. Ensure that you cautiously make updates to the default settings.

4. Choose the required **Optimized Roaming Date Rate Threshold**. The threshold value options are different for 802.11a, 802.11b, and 802.11ax networks.

   Optimized roaming disassociates clients based on the RSSI of the client data packet and data rate. The client is disassociated if the current data rate of the client is lower than the Optimized Roaming Data Rate Threshold.

5. In the **Optimized Roaming Hysteresis** field, enter the hysteresis value. The the range is from 0 to 10. The default is 6.
6. Click **Apply** to save the configuration.

Optimized roaming is configured and will manage client disassociation based on the specified thresholds and settings.

Configure optimized roaming (CLI)

Configure optimized roaming using commands.

Enable optimized roaming to improve client connectivity and reduce roaming delays by automatically triggering roaming decisions based on data rate thresholds.

Optimized roaming helps wireless clients move seamlessly between access points when their connection quality degrades below specified thresholds. This feature is particularly useful in high-density environments where clients need to maintain optimal connectivity.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure 802.11a, 802.11b, or 802.11 6-GHz optimized roaming.

   Example

   ```
   Device(config)# ap dot11 band rrm optimized-roam
   ```

Example

```
Device(config)# ap dot11 24ghz rrm optimized-roam
```

By default, optimized roaming is disabled. The *band* can be 24-GHz, 5-GHz, or 6-GHz.

3. Configure the data rate threshold for 802.11b for optimized roaming.

Example

```
Device(config)# ap dot11 24ghz rrm monitor optimized-roam data-rate-threshold
 threshold-value
```

Example

```
Device(config)# ap dot11 24ghz rrm monitor optimized-roam data-rate-threshold
 18M
```

Valid threshold values for 24-GHz: 1M, 2M, 5_5M, 6M, 9M, 11M, 12M, 18M, 24M, 36M, 48M, 54M, or disable.

4. Configure the data rate threshold for 802.11a or 802.11 6-GHz optimized roaming.

Example

```
Device(config)# ap dot11 band rrm monitor optimized-roam data-rate-threshold
 threshold-value
```

Example

```
Device(config)# ap dot11 6ghz rrm monitor optimized-roam data-rate-threshold
 18M
```

Valid threshold values for 5-GHz and 6-GHz: 6M, 9M, 12M, 18M, 24M, 36M, 48M, 54M, or disable.

5. Display the 802.11a, 802.11b, or 802.11 6-GHz optimized roaming configurations.

Example

```
Device# show ap dot11 band optimized-roaming statistics
```

Example

```
Device# show ap dot11 24ghz optimized-roaming statistics
```

Optimized roaming is now configured with the specified data rate thresholds, enabling automatic client roaming when connection quality degrades below the configured values.

50 Cisco Flexible Radio Assignment

Topics:

- Flexible radio assignment actions

Flexible radio assignment actions

Describes FRA Action functionality, guiding users through configuration in default and 2.4-GHz RF profiles via CLI and outlining procedures to verify FRA Action deployments for optimal wireless performance.

Flexible Radio Assignment (FRA) evaluates 2.4-GHz radio coverage to identify overlapping coverage causing radio interference. If there is an overlapping coverage, the dual-band radio moves to either 5-GHz client serving or monitor role.

Feature history for flexible radio assignment action
Table 65: Feature history for FRA Action

Release	Feature	Feature information
Cisco IOS XE Dublin 17.10.1	Flexible Radio Assignment (FRA) Action	In Cisco IOS-XE 17.10.1 and earlier releases, the FRA moves the redundant dual-band radios to either 5-GHz client-serving role or monitor role.
Cisco IOS XE Dublin17.11.1	Flexible Radio Assignment (FRA) Action	From Cisco IOS-XE 17.11.1 onwards, you can select the redundant dual-band radios in a network to operate in monitor only mode.

Release Information

In Cisco IOS-XE 17.10.1 and earlier releases, the FRA moves the redundant dual-band radios to either 5-GHz client-serving role or monitor role. From Cisco IOS-XE 17.11.1 onwards, you can set redundant dual-band radios in a network to operate in monitor-only mode.

> **Note**
>
> The FRA action feature is disabled by default.

Configure FRA action in default RF profile (CLI)

Configure the FRA action in the default RF profile to optimize radio frequency management.

Procedure

1. Configure terminal

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Configure the FRA action

Example

```
Device(config)# ap dot11 24ghz fra action monitor
```

Configures the FRA action to monitor mode, moving all redundant dual-band APs solely to the monitor role.

3. Exit configuration mode

Example

```
Device(config)# end
```

Exits configuration mode and returns to privileged EXEC mode.

Upon completion, the FRA action is set, redundancy in dual-band radios is handled efficiently, and the system returns to privileged EXEC mode.

Configure FRA action in 2.4-GHz RF profile (CLI)

Configure FRA action in 2.4-GHz RF profile using commands.

Procedure

---

1. Configure terminal

Example

```
Device# configure terminal
```

Enters global configuration mode

2. Configure the RF profile name

Example

```
Device(config)# ap dot11 24ghz rf-profile alpha-rfprofile-24ghz
```

Configures the RF profile name and enters RF profile configuration mode.

3. Configure the FRA action as monitor

Example

```
Device(config-rf-profile)# fra action monitor
```

Configures the FRA action as monitor, and moves all redundant dual-band radios to monitor role only.

4. Exit configuration mode

Example

```
Device(config-rf-profile)# end
```

Exits configuration mode and returns to privileged EXEC mode.

Verify FRA action configuration

To view the selected FRA action, use the following command:

```
Device# show ap fra
FRA State               : Enabled
FRA Freeze              : Disabled
FRA Operation State     : Up
FRA Sensitivity         : higher (85%)
FRA Interval            : 1 Hour(s)
Service Priority        : Coverage
Client Aware FRA        : Enabled
  Client Select         : 25%
  Client Reset          : 5%
FRA Action              : 2.4GHz/Monitor
  Last Run              : 3069 seconds ago
```

To view the FRA action details in an AP RF profile, use the following command:

```
Device# show ap rf-profile name madhu-rf-profile-24 detail | sec FRA
Client Aware FRA                  : Disabled
FRA Action                        : 2.4GHz/Monitor
```

To view the radio mode and role in an AP, use the following command:

```
Device# show ap name AP7872.5DED.CB74 config slot 0 | sec Attribute
Attributes for Slot 0
  Radio Type                                    : 802.11n - 2.4/5 GHz
  Radio Mode                                    : Monitor
  Radio Role                                    : Monitor
    Assignment Method                           : Auto
    Monitor Mode Reason                         : Automatically Switched by
FRA
```

51 XOR Radio Support

Topics:

- Dual-band radios in Cisco AP models

Dual-band radios in Cisco AP models

Details on dual-band radio support.

A dual-band radio is a device category that

- offers connectivity on more than one frequency band (such as 2.4 GHz and 5 GHz)
- provides flexibility in network configuration, and
- is used in multiple Cisco AP models like the 2800, 3800, 4800, and 9120 series.

Feature history table

Table 66: Feature history table for dual-band radios in Cisco AP models

Feature name	Release information	Feature description
Dual-band (XOR) radio support	Cisco IOS XE 16.10.1	The Dual-band (XOR) radio support offers the ability to serve 2.4 GHz or 5 GHz bands or passively monitor both the bands on the same AP. These APs can be configured to serve clients in 2.4 GHz and 5 GHz bands, or serially scan both 2.4 GHz and 5 GHz bands on the flexible radio while the main 5 GHz radio serves clients.

Key features of dual-band radios in Cisco APs

The XOR radio support can be steered manually or automatically.

- Manual steering of a band on a radio: The band on the XOR radio can only be changed manually.
- Automatic client and band steering on radios: This is managed by the Flexible Radio Assignment (FRA) feature that monitors and changes the band configurations as per site requirements.

Client steering

When a radio moves between bands (from 2.4 GHz to 5 GHz and vice versa), clients need to be steered to get an optimal distribution across radios. When an AP has two radios in the 5 GHz band, client steering algorithms contained in the FRA algorithms are used to steer a client between the same band co-resident radios

Cisco APs and dual-band radios

Cisco 2800, 3800, 4800, and 9120 series AP models are equipped with dual-band (XOR) radios. These models have

- radios that operate on either 2.4 GHz or 5 GHz bands, or
- the ability to passively monitor both the bands on the same AP.

These APs can be configured to serve clients in 2.4 GHz and 5 GHz bands, or serially scan both 2.4 GHz and 5 GHz bands on the flexible radio while the main 5 GHz radio serves clients.

Cisco AP models up to the Cisco 9120 APs are designed to support dual 5 GHz band operations with the *i* model supporting a dedicated Macro or Micro architecture and the *e* and *p* models supporting Macro or Macro. The Cisco 9130AXI APs support dual 5 GHz operations as Macro or Micro cell.The CW9166I supports Macro or Macro cell.

Cisco Catalyst Wireless 9166 AP (CW9166) has XOR function for a dual 5 GHz 4x4 or 5 GHz 4x4 and 6 GHz 4x4 radios. These radios can also be configured as client serving, monitor or as a sniffer interface like the earlier XOR radios.

> **Note**
>
> For all countries that do not support 6 GHz spectrum for use of Wi-Fi, when the Cisco Catalyst Wireless 9166I AP operates as dual 5 GHz, the 5 GHz channels will be locked on both the radios even if slot 2 is disabled or set up for monitoring.

Wi-Fi 7 APs compatibility

For Wi-Fi 7 APs, the XOR radio operates in 2.4 GHz or 5 GHz low band mode (UNII 1-2A). By default, the XOR radio is brought up in 2.4 GHz band. The existing controller dual-band commands are used to switch between 2.4 GHz and 5 GHz bands. When XOR radio is switched to 5 GHz band, the Wi-Fi 7 APs operate in dual 5 GHz mode. To provide enough RF isolation between both 5 GHz radios, both the 5 GHz radios operate in band-locked mode and radio frequency.

Limitations

Limitations for XOR radio support.

These are the limitations for XOR radio support:

- RF measurement is disabled when a static channel is configured on slot 1. As a result, the dual-band radio slot 0 operates only with 5 GHz radios and not in the monitor mode. When slot 1 radio is disabled, RF measurement will not run, and the dual band radio slot 0 will be only on 2.4 GHz radio.
- Only one of the 5 GHz radios can operate in the UNII band (100 to 144), due to an AP limitation to maintain the power budget within the regulatory limit.

Configure default XOR radio support (CLI)

Configure Default XOR Radio Support using commands.

Complete this task to configure the basic settings for XOR radio support.

Before you begin

> **Note**
>
> The default radio points to the XOR radio hosted on slot 0.

Procedure

1. Enable the priviledged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Configure the 802.11 dual-band external antenna gain on the AP.

Example

```
Device# ap name ap-name  dot11 dual-band antenna ext-ant-gain
antenna_gain_value
```

Enter external antenna gain value in multiple of .5 dBi units (that is, an integer value 4 means 4 x 0.5 = 2 dBi of gain).

3. Shut down the default dual-band radio.

Example

```
Device# ap name ap-name  dot11 dual-band shutdown
```

Use the **no** form of the command to enable the radio.

4. Switch to the client-serving mode of the AP.

Example

```
Device# ap name ap-name  dot11 dual-band role manual client-serving
```

5. Switch to the 2.4 GHz radio band.

Example

```
Device# ap name ap-name  dot11 dual-band band 24ghz
```

The basic configuration of the XOR radio is completed.

Example

```
Device> enable
Device# ap name ap-name  dot11 dual-band antenna ext-ant-gain 2
Device# ap name ap-name  dot11 dual-band shutdown
Device# Device# ap name ap-name  dot11 dual-band role manual client-serving
Device# Device# ap name ap-name  dot11 dual-band band 24ghz
```

What to do next

Continue with the configuration steps listed in the "Configure advanced settings" to complete the configuration.

Configure advanced settings (CLI)

Complete this task to configure the advanced settings for XOR radio support, such as, transmit power, channel, channel width, CleanAir settings and so on.

Procedure

---

1. Configure the transmit power for the radio on the AP.

Example

```
Device# ap name ap-name  dot11 dual-band txpower {transmit_power_level | auto}
```

> **Note**
>
> When an FRA-capable radio (slot 0 on 9120 AP[for instance]) is set to Auto, you cannot configure static channel and Txpower on this radio.
>
> If you want to configure static channel and Txpower on this radio, you will need to change the radio role to Manual Client-Serving mode.
>
> This note is not applicable for Cisco Catalyst Wireless 9166 AP (CW9166).

2. Configure the channel number for the dual band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel 40
   ```

   The range of the *channel-number* is from 1 to 173.

3. Optional: Enable the auto channel assignment for the dual-band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel auto
   ```

4. Configure the channel width for the dual band.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band channel width {20 MHz | 40 MHz | 80
    MHz | 160 MHz}
   ```

5. Enable the Cisco CleanAir management on the dual-band radio.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band cleanair
   ```

6. Configure a band for the Cisco CleanAir feature.

   Example

   ```
   Device# ap name ap-name [no] dot11 dual-band cleanair band 5 GHz
   ```

   Selects a band for the Cisco CleanAir feature.

   Use the **no** form of this command to disable the Cisco CleanAir feature.

7. Configure the 802.11n dual-band antenna and antenna ports selection for a specific AP.

   Example

   ```
   Device# ap name ap-name  dot11 dual-band dot11n antenna {A | B | C | D}
   ```

Here, A, B, C, and D are the antenna ports.

The configuration of the additional features for dual-band (XOR) radios are completed.

Example

```
Device# ap name ap-name  dot11 dual-band txpower auto
Device# ap name ap-name  dot11 dual-band channel 40
Device# ap name ap-name  dot11 dual-band channel width 40 MHz
Device# ap name ap-name  dot11 dual-band cleanair
Device# ap name ap-name [no] dot11 dual-band cleanair band 5 GHz
Device# ap name ap-name  dot11 dual-band dot11n antenna A
```

Configure XOR radio support for the specified slot number (GUI)

Configure XOR radio support for the specified slot number using GUI.

Complete this task to configure XOR radio for the specified slot number.

Procedure

---

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. In the **Dual-Band Radios** section, select the AP for which you want to configure dual-band radios.

   The AP name, MAC address, CleanAir capability and slot information for the AP are displayed. If the Hyperlocation method is HALO, it displays the antenna PID and antenna design specifics.
3. Click **Configure**.
4. In the **General** tab, set the **Admin Status** as required.
5. Set the **CleanAir Admin Status** field to Enable or Disable.
6. Click **Update & Apply to Device**.

The XOR radio support for the specified slot number has been configured.

Configure XOR radio support for the specified slot number (CLI)

Configure XOR Radio Support for the Specified Slot Number using commands.

Complete this task to configure XOR radio for a specified slot number.

Procedure

---

1. Enable the priviledged EXEC mode.

   Example

   ```
   Device> enable
   ```
2. Configure dual-band antenna for the XOR radio hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 antenna ext-ant-gain
external_antenna_gain_value
```

Here, *external_antenna_gain_value* is the external antenna gain value in multiples of .5 dBi unit. The range is from 0 to 40.

> **Note**
>
> - For APs supporting self-identifying antennas (SIA), the gain depends on the antenna, and not on the AP model. The gain is learned by the AP and there is no need for controller configuration.
> - For APs that do not support SIA, the APs send the antenna gain in the configuration payload, where the default antenna gain depends on the AP model.

3. Configure the current band for XOR radio hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 band {24ghz | 5ghz}
```

4. Configures dual-band channel for the XOR radio hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 channel {channel-number | auto
 | width [160 | 20 | 40 | 80]}
```

The range of the *channel_number* is from 1 to 165.

5. Enable the Cisco CleanAir feature for dual-band radios hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 cleanair band {24Ghz | 5ghz}
```

6. Configure 802.11n dual-band parameters hosted on slot 0 for a specific AP.

Example

```
Device# ap name ap-name dot11 dual-band slot 0 dot11n antenna {A | B | C |
D}
```

Here are the antenna configurations.

A : Enables antenna port A.

B : Enables antenna port B.

C : Enables antenna port C.

D : Enables antenna port D.

7. Configure dual-band role for the XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 role {auto | manual
   [client-serving | monitor]}
   ```

   Here are the dual-band roles.

   - **auto** : refers to the automatic radio role selection.
   - **manual** : refers to the manual radio role selection.

   Note

   When Flexible Radio Assignment (FRA) is disabled, XOR radios whose roles were changed by Radio Resource Management (RRM) might not automatically revert to their default radio role. To restore an individual AP to the default client-serving role, use the these commands:

   ```
   Device# ap name ap-name dot11 dual-band slot 0 shutdown
   ```

   ```
   Device# ap name ap-name dot11 dual-band slot 0 role manual client-serving
   ```

   ```
   Device# ap name ap-name dot11 dual-band slot 0 band 24ghz
   ```

   ```
   Device# ap name ap-name no dot11 dual-band slot 0 shutdown
   ```

8. Disable dual-band radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name [no] dot11 dual-band slot 0 shutdown
   ```

   Use the **no** form of this command to enable the dual-band radio.

9. Configure dual-band transmit power for XOR radio hosted on slot 0 for a specific AP.

   Example

   ```
   Device# ap name ap-name dot11 dual-band slot 0 txpower {tx-power-level | auto}
   ```

   Here,

   - *tx_power_level* : is the transmit power level in dBm. The range is from 1 to 8.

- **auto** : enables auto-RF.

The XOR radio for the specified slot number is configured.

Example

```
Device> enable
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 antenna
ext-ant-gain 2
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 band 24ghz

                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 channel 3
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 cleanair
band 24Ghz
                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 dot11n
antenna A
              Device# ap name AP-SIDD-A06 [no] dot11 dual-band slot 0 shutdown

                Device# ap name AP-SIDD-A06 dot11 dual-band slot 0 txpower 2
```

Verify XOR radio support

To verify the XOR radio support parameters, use these **show** commands:

Verify auto-RF information

To display the auto-RF information for a Cisco AP, use the **show ap name** *ap-name* **auto-rf dot11 dual-band** command.

```
Device# show ap name cisco-ap-name auto-rf dot11 dual-band
```

Verify the list of BSSIDs

To display the list of BSSIDs for a Cisco AP, use the **show ap name** *ap-name* **wlan dot11 dual-band** command.

52 Cisco Receiver Start of Packet

Topics:

- Receiver start of packet detection threshold

Receiver start of packet detection threshold

Explains what receiver start of packet detection thresholds are and how they impact wireless network performance and client distribution.

A receiver start of packet (Rx SOP) detection threshold is a wireless radio configuration setting that

- determines the Wi-Fi signal level (measured in dBm) at which an APs radio demodulates and decodes a received packet
- affects radio sensitivity and the effective size of the receiver cell, and
- influences how clients are distributed across APs within a wireless network.

Rx SOP is used to address clients with weak RF links, sticky clients, and to support client load balancing across APs. Rx SOP helps optimize network performance in high-density deployments, such as stadiums and auditoriums. In these environments, APs need to prioritize the nearest and strongest clients.

Restrictions for Rx SOP

Rx SOP Restrictions.

- Rx SOP configuration does not apply to the third radio module pluggable on Cisco Aironet 3600 Series APs.
- Rx SOP configurations are supported only in Local, FlexConnect, Bridge, and Flex+Bridge modes.
- Rx SOP configurations are not supported in the FlexConnect+PPPoE, FlexConnect+PPPoE-wIPS, and FlexConnect+OEAP submodes.

Permitted range for the Rx SOP threshold

This table shows the allowed Rx SOP (Receiver Start of Packet) threshold settings.

- It is for different radio bands and threshold levels.

Table 67: Rx SOP Threshold

Radio Band	Threshold High	Threshold Medium	Threshold Low
2.4 GHz	-79 dBm	-82 dBm	-85 dBm
5 GHz	-76 dBm	-78 dBm	-80 dBm

Known behavior

Regardless of the radio mode, the controller sets the radio with the specified RX-SOP value. The AP then decides whether to use this value.

- For the XOR radio (Slot 0), when the AP is in monitor mode, the RX-SOP value sent to the AP depends on the frequency band used before switching to monitor mode. If the radio operated in the 2.4 GHz band, the RX-SOP parameters are selected from the 2.4 GHz RF profile or the default RF profile. If it operated in the 5 GHz band, the RX-SOP parameters are chosen from the 5 GHz RF profile or the default RF profile configured for the AP.

Configure Rx SOP (CLI)

Configure Rx SOP using commands.

Adjust the Rx SOP threshold for high-density Wi-Fi environments.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   DeviceDevice# configure terminal
   ```

2. Configure the 802.11bg or 802.11a radio Rx SOP threshold.

   Example

   ```
   DeviceDevice(config)# ap dot11 {24ghz | 5ghz} rx-sop threshold {auto | custom
    | high | low | medium}
   ```

3. Return to the privileged EXEC mode.

   Example

   ```
   Device# end
   ```

4. Display the 802.11bg or 802.11a high-density parameters.

   Example

   ```
   DeviceDevice# show ap dot11 {24ghz | 5ghz} high-density
   ```

5. Display the summary of all the connected Cisco APs.

   Example

   ```
   DeviceDevice# show ap summary
   ```

Customize RF profile (CLI)

Customize RF profile using commands.

Customize 802.11 RF profile parameters.

Procedure

1. Enter the global configuration mode.

Example

```
DeviceDevice# configure terminal
```

2. Configure the 802.11bg, 802.11a or 802.11 6-GHz high-density parameters.

Example

```
DeviceDevice(config-rf-profile)# high-density rx-sop threshold {auto | custom
 | high | low | medium}
```

3. Display the summary of all the connected Cisco APs.

Example

```
DeviceDevice# show ap summary
```

4. Return to the privileged EXEC mode.

Example

```
Device# end
```

53 Client Limit

Topics:

- Client limits

Client limits

Describes client connection constraints, specifying maximum supported clients per platform, recommended usage thresholds, and best practices for maintaining reliable client operations.

A client limit is a wireless network feature that

- enforces a maximum number of client devices that can connect to an AP, and
- allows you to configure the client cap per AP radio or per WLAN.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 68: Feature history for client limits

Feature Name	Release Information	Feature Description
Client Limit and Delete	Cisco IOS XE Dublin 17.8.x	From this release, client limiting is supported per AP, per radio, and per AP-radio per WLAN. Client limiting is supported on the Cisco Catalyst 9136 Series APs in FlexConnect mode. The following commands are introduced: • association-limit • high-density clients count
Client limits	Cisco IOS XE Gibraltar 16.10.x	This feature enforces a maximum number of client devices per AP, supporting per-AP, per-radio, and per-WLAN configurations.

Limitations

Client limit limitations.

- All APs except the Cisco Catalyst 9136 Series support only 200 clients per radio. If you configure more than 200 clients for these APs, the AP radios can still support only 200 clients based on the AP capability value.
- Client limiting is supported on the Cisco Catalyst 9136 Series APs in FlexConnect mode.

Configure client limit per WLAN (GUI)

Configure client limit per WLAN using GUI.

Restrict the number of client devices that can connect to a specific WLAN.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.

2. Click a WLAN from the list of WLANs.
3. Click the **Advanced** tab.
4. Under the **Max Client Connections** settings, enter the client limit for **Per WLAN**, **Per AP Per WLAN**, and **Per AP Radio Per WLAN**.
5. Click **Update & Apply to Device**.

Configure client limit per WLAN (CLI)

Configure client limit per WLAN using commands.

Set the maximum number of clients permitted to associate with a specific WLAN, AP, or AP radio using CLI commands.

Procedure

1. Enter the privileged EXEC and the global configuration mode.

   Example

   ```
   Device# enable
   Device# configure terminal
   ```

2. Specify the WLAN name.

   Example

   ```
   Device(config)# wlan <wlan-profile-name>
   ```

   WLAN needs to be shut down in order to change the client limit parameters.

3. Configure the maximum number of clients that is associated to the given WLAN.

   Example

   ```
   Device(config-wlan)# client association limit <maximum-client-per-WLAN>
   ```

   Note

   Depending on the primary AP in the Cisco Embedded Wireless Controller network, the maximum number of clients supported varies.

4. Configure the maximum number of clients that is associated to an AP in the WLAN.

   Example

   ```
   Device(config-wlan)# client association limit ap <max-clients-per-AP-per-WLAN>
   ```

   The valid range is between zero and 1200 clients. The default value is zero.

> **Note**
>
> A Cisco Catalyst 9136 Series AP can support a maximum of 1200 clients.

5. Configure the maximum limit of clients that is associated to an AP radio in the WLAN.

   Example

   ```
   Device(config-wlan)# client association limit radio
   <maximum-clients-per-AP-radio-per-WLAN>
   ```

   The valid range is between zero to 500 clients. The default value is 200.

   > **Note**
   >
   > A Cisco Catalyst 9136 Series AP radio can support a maximum of 400 clients.

6. Return to the privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

7. Verify the current configuration of the WLAN and the corresponding client association limits.

   Example

   ```
   Device# show wlan id wlan-id 2
   ```

Configure client limit per AP (GUI)

Configure client limit per AP using GUI.

Set a limit on the number of clients that can associate with each AP.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. Click **Add**.
3. In the **General** tab, enter the name and description of the corresponding AP join profile.
4. Click the **Client** tab.
5. In the **Maximum Client Limit** field, enter the maximum client associations per AP. The valid values are between zero and 1200. The default value is zero.

6. Click **Apply to Device**.

Configure client limit per AP (CLI)

Configure client limit per AP using commands.

Set a limit on the maximum number of client devices allowed to associate with a single AP.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Configure the maximum client connections per AP.

   Example

   ```
   Device(config-ap-profile)# association-limit <max-client-connections>
   ```

   The default value is zero.

   > **Note**
   >
   > A Cisco Catalyst 9136 Series AP can support a maximum of 1200 clients.

4. Return to the privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

Configure client limit per radio (GUI)

Configure client limit per radio using GUI.

Set a maximum number of client connections per AP radio for an RF profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. In the **RF** tab, click the required RF profile name from the displayed list of RF profiles.

   The **Edit RF Profile** page is displayed.
3. Click the **Advanced** tab.
4. Under the **High Density Parameters** section, in the **Max Clients** field, enter the maximum number of client connections per AP radio. The valid range is between zero and 500. The default value is 200 client connections.
5. Click **Update (and) Apply to Device**.

Configure client limit per radio (CLI)

Configure client limit per radio using commands.

Limit the number of client devices that can associate with each AP radio.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Configure the RF profile and enter the RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} rf-profile rf-profile-name
   ```
3. Configure the maximum number of client connections per AP radio.

   Example

   ```
   Device(config-rf-profile)# high-density clients count
   <maximum-client-connections>
   ```

   The valid range is between zero and 400. The default value is 200 client connections.

   > **Note**
   >
   > A Cisco Catalyst 9136 Series AP radio can support a maximum of 400 clients.

4. Return to the privileged EXEC mode. Alternatively, you can also press **Ctrl-Z** to exit global configuration mode. **end**

Example

```
Device(config)# end
```

Verify client limit

Verify client limit.

To verify client limit in local mode, run the following command:

```
Device# show wireless stats client delete reasons | sec Max
                Maximum client limit reached on AP                  : 0
                Maximum client limit reached on AP per wlan         : 0
                Maximum client limit reached on AP radio per wlan   : 0
                Maximum client limit reached on AP radio            : 0
```

To verify client limit in the FlexConnect central authentication mode, run the following command:

```
Device# show wireless stats client delete reasons | sec max
                AP limiting maximum client per AP               : 0
                AP limiting maximum client per AP radio per wlan : 0
                AP limiting maximum client per AP radio          : 0
```

54 IP Theft

Topics:

- IP theft
- SAE client exclusion visibility

IP theft

Introduces the fundamental principles of IP theft, including the types of intellectual property at risk, common methods of theft, and the impact on organizations.

An IP Theft feature is a wireless controller security mechanism that

- detects duplicate IP address usage among connected clients
- assigns precedence to clients based on a defined preference order, and
- blocks or excludes clients attempting to use IP addresses already assigned to others.

The IP Theft feature is enabled by default on the controller. If a wireless client tries to use an IP address assigned to a wired client, the controller marks it as a theft attempt.

Lower the idle timeout to prevent false IP theft

Lower the idle timeout for devices that may switch WLANs while out of range to prevent incorrect IP theft events.

When a device moves between WLANs while out of range of APs, it may retain the same IPv6 link-local address but present a different MAC address. Because the controller cannot immediately detect the move, it may interpret the reuse of the same IP address as an IP theft event.

To avoid this, lower the idle timeout value so the controller can promptly remove stale client entries from the original WLAN. This helps ensure that address reuse by legitimate roaming devices is not mistakenly treated as a theft attempt.

IP preference levels for IP theft detection

The controller uses IP preference levels to resolve conflicts when multiple clients claim the same IP address. These levels determine which client has priority based on the method used to learn the IP address. Preference order for IPv4 clients:

- DHCPv4
- ARP
- Data packets

Preference order for IPv6 clients:

- DHCPv6
- NDP (Neighbor Discovery Protocol)
- Data packets

Additional rules:

- Static wired clients always receive higher preference than dynamically assigned clients.
- Wired clients are prioritized over wireless clients when IP conflicts occur.

Configure IP theft (GUI)

Configure IP theft using GUI.

Prevent unauthorized use or reuse of IP addresses by configuring IP theft protections.

Procedure

1. Choose **Configuration** > **Security** > **Wireless Protection Policies** > **Client Exclusion Policies**.
2. Check the **IP Theft or IP Reuse** check box.
3. Click **Apply**.

Configure IP theft (CLI)

Configure IP theft using commands.

Enable IP theft detection and configure client exclusion policies using CLI.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the client exclusion policy.

   Example

   ```
   Device(config)# wireless wps client-exclusion ip-theft
   ```

Configure the IP theft exclusion timer (CLI)

Configure the IP theft exclusion timer using commands.

Set the exclusion timer to temporarily block IP addresses suspected of theft on a WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy profile-policy default-policy-profile
   ```

3. Specify the timeout, in seconds.

Example

```
Device(config-wireless-policy)# exclusionlist timeout time-in-seconds
```

The valid range is from zero-2147483647. Enter zero for no timeout.

Add static entries for wired hosts (CLI)

Add static entries for wired hosts.

Configure static wired bindings for devices on a VLAN to control IP address and interface assignment.

> **Note**
>
> If you configure wired bindings and SVI IP addresses on the device, the device uses those instead of DHCP.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the IPv4 or IPv6 static entry.

   Example

   ```
   Device(config)# device-tracking binding vlan vlan-id 20 ipv4-address 20.20.20.5
    interface gigabitEthernet ge-intf-num 1 hardware-or-mac-address 0000.1111.2222
   ```

   Example

   ```
   Device(config)# device-tracking binding vlan vlan-id 20 ipv6-address
   2200:20:20::6 interface gigabitEthernet ge-intf-num 1 hardware-or-mac-address
    0000.444.3333
   ```

   Use the first option to configure an IPv4 static entry or the second option to create an IPv6 static entry.

Verify IP theft configuration

Verify IP theft configuration.

Use the command to check if the IP theft feature is enabled or not:

```
Device# show wireless wps summary

Client Exclusion Policy
```

```
  Excessive 802.11-association failures   : Enabled
  Excessive 802.11-authentication failures: Enabled
  Excessive 802.1x-authentication         : Enabled
  IP-theft                                : Enabled
  Excessive Web authentication failure    : Enabled
  Cids Shun failure                       : Enabled
  Misconfiguration failure                : Enabled
  Failed Qos Policy                       : Enabled
  Failed Epm                              : Enabled
```

Use the commands to view additional details about the IP theft feature:

```
Device# show wireless client summary

Number of Local Clients: 1

MAC Address    AP Name                WLAN State              Protocol Method
     Role
-------------------------------------------------------------------------------
000b.bbb1.0001 SimAP-1                2    Run                11a      None
     Local

Number of Excluded Clients: 1

MAC Address    AP Name                WLAN State              Protocol Method

-------------------------------------------------------------------------------
10da.4320.cce9 charlie2               2    Excluded           11ac     None
```

```
Device# show wireless device-tracking database ip

IP                              VLAN  STATE       DISCOVERY   MAC
  ------------------------------------------------------------------------
  20.20.20.2                     20    Reachable   Local       001e.14cc.cbff

  20.20.20.6                     20    Reachable   IPv4 DHCP   000b.bbb1.0001
```

```
Device# show wireless exclusionlist

Excluded Clients

Protocol: 802.11ac
AP MAC Address : 58ac.780e.08f0
AP Name: charlie2
AP slot : 1
Wireless LAN Id : 2
Wireless LAN Name: mhe-ewlc
VLAN Id : 20
```

SAE client exclusion visibility

Introduces SAE client exclusion visibility, enabling controllers to access client exclusion list data in Flex central authentication deployments with SAE-enabled WLANs, and reducing the need for manual log collection for enhanced operational efficiency.

SAE client exclusion visibility is a feature that

- addresses a limitation in Flex central authentication deployments with SAE-enabled WLANs
- makes client exclusion list data available on the controller, and
- reduces manual log collection for customers.

In FlexConnect central authentication deployments with SAE enabled WLANs, the controller does not have access to client exclusion list data because SAE authentication messages are processed at the AP, and authentication failures are not reported to the controller. As a result, you must collect logs manually, which increases operational costs. This feature provides a solution to this issue.

This feature addresses only Flex central authentication, WPA3 + SAE/FT-SAE/SAE-EXT-KEY/FT-SAE- EXT-KEY WLANs.

Feature history for SAE client exclusion visibility
Table 69: Feature history

Feature Name	Release Information	Feature Description
SAE client exclusion visibility	Cisco IOS XE 17.18.2	The SAE authentication client exclusion feature overcomes the limitations of Flex central authentication deployments with SAE-enabled WLANs. The feature reports client authentication failures and exclusion data to the controller. It generates syslog messages for these events and allows administrators to configure the duration that a client remains excluded. It centralizes troubleshooting information that was previously only available on individual APs, reducing the need for manual log collection.

Configure client exclusion timeout (GUI)

To set the duration for which a client remains excluded from the system using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. In the **General** tab, specify the name and description for the policy profile.
3. Click the **Advanced** tab.
4. In the **WLAN Timeout** section, enter a value for the **Client Exclusion Timeout** field, in seconds. This option is enabled by default. The valid range is 0 to 2,147,483,647 seconds. The default is 60 seconds.
5. Click **Apply to Device**.

The system enables and configures the SAE authentication client exclusion feature for the selected wireless policy profile.

What to do next

Monitor excluded clients.

Monitor client exclusion

Monitor excluded clients.

Procedure

1. Choose **Monitoring** > **Wireless** > **Clients**.
2. Click the **Excluded Clients** tab.
   The excluded clients and their details are listed on this page. Additionally, you can add an excluded client by clicking the **Add** button and entering the MAC address and the description.

Configure client exclusion timeout (CLI)

Set the duration for which a client remains excluded from the system.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a policy profile for the WLAN.

   Example

   ```
   Device# wireless profile policy policy-profile-name
   ```

   Replace `policy-profile-name` with the name of your wireless policy profile. For example, `flex-profile-policy`.

3. Disable central DHCP for locally switched clients.

   Example

   ```
   Device(config-wireless-policy)# no central dhcp
   ```

4. Disable central switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

5. Enable or disable exclusion listing on the WLAN by setting the exclusion time for the client. This feature is enabled by default.

   Example

   ```
   Device(config-wireless-policy)# [no] exclusionlist timeout seconds
   ```

   The timeout is set in seconds. The default is 60 seconds. The valid range is from 0 to 2,147,483,647 seconds. If you set the value to 0, the client remains excluded indefinitely.

   Use the **no** form of this command to disable the feature.

The specified exclusion timeout is applied to the WLAN policy profile. This duration determines how long the excluded clients remain unable to connect.

```
Device# configure terminal
Device(config)# wireless profile policy default-policy-profile
Device(config-wireless-policy)# no central dhcp
Device(config-wireless-policy)# no central switching
Device(config-wireless-policy)# [no] exclusionlist timeout 60
```

Verify client exclusion data

Verify client exclusion data using these commands.

Verify the wireless policy profile information, including the exclusion status and timeout for clients, using this command:

```
Device# show wireless profile policy detailed flex-profile-policy
WLAN Switching Policy
  Flex Central Switching            : DISABLED
  Flex Central Authentication       : ENABLED
  Flex Central DHCP                 : DISABLED
  Flex NAT PAT                      : DISABLED

Exclusionlist Params
  Exclusionlist                     : ENABLED
  Exclusion Timeout                 : 60
```

View a summary of wireless clients, including information about excluded clients, using this command:

```
Device# show wireless client summary
Number of Clients: 0
Number of Excluded Clients: 1
MAC Address AP Name Type ID State Protocol Method
 ------------------------------------------------------------------------------------------

90XX.84XX.63XX WLAN 3 Excluded N/A None
```

Verify the list of excluded wireless clients using this command:

```
Device# show wireless exclusionlist
Number of Excluded Clients : 1
MAC Address Description Exclusion Reason Time Remaining
------------------------------------------------------------------------------------------------

90XX.84XX.63XX          SAE authentication failure 49
```

55 Unscheduled Automatic Power Save Delivery

Topics:

- Unscheduled automatic power save delivery overview

Unscheduled automatic power save delivery overview

Introduces the fundamentals of power save delivery, then guides users through configuring Power Save (U-APSD) using CLI to optimize wireless device energy efficiency.

Unscheduled automatic power save delivery (U-APSD) is a power-saving mechanism that

- is defined as a QoS facility in IEEE 802.11e standards
- delivers multiple downlink packets in response to a single uplink trigger, and
- reduces wireless latency and extends mobile device battery life

Additional information

- U-APSD activates automatically when WMM (Wi-Fi Multimedia) is enabled.
- U-APSD eliminates the need for polling individual packets at the access point.

Possible sequence for U-APSD operation:

A client device sends a single uplink trigger packet. In response, the access point delivers multiple queued downlink packets based on that single trigger.

View unscheduled automatic power save delivery

View unscheduled automatic power save delivery using commands.

Show detailed information of a client by MAC address.

```
Device# show wireless client mac-address 2B:5B:B3:18:56:E9 detail
Output Policy State : Unknown
Output Policy Source : Unknown
WMM Support : Enabled
U-APSD Support : Enabled
U-APSD value : 15
APSD ACs    : BK(T/D), BE, VI(T/D), VO(T/D)
Power Save : OFF
Current Rate :

--------------------------
BK : Background
BE : Best Effort
VI : Video
VO : Voice.

T: UAPSD Trigger Enabled
D: UAPSD Delivery Enabled
T/D : UAPSD Trigger and Delivery Enabled
```

56 Target Wake Time

Topics:

- Target wake time

Target wake time

Target Wake Time details.

Target wakeup time (TWT) is a power-saving mechanism that

- allows an AP to schedule specific times for devices or stations (STAs) to wake up and communicate
- enables those devices to remain in a power-saving state for longer periods, and
- reduces overall network congestion.

Feature history

Table 70: Feature history for target wake time

Feature name	Release information	Feature description
Target wake time	Cisco IOS XE 17.2.1	Target wake time (TWT) allows an AP to manage activity in the Wi-Fi network, in order to minimize medium contention between Stations (STAs), and to reduce the required amount of time that an STA in the power-save mode needs to be awake. This is achieved by allocating STAs to operate at non-overlapping times, and/or frequencies, and concentrate the frame exchanges in predefined service periods.

Delivery traffic indication map

Unscheduled automatic power-save delivery

With 802.11e, the new power-saving mechanism was introduced that helps voice-capable Wi-Fi devices, as voice packets are transmitted at short time intervals, typically 20 ms/sec.

The existing Wi-Fi client power-saving mechanisms have been in use since 802.11b, where the client devices sleep between AP beacons or multiple beacons, waking up only when they have data to transmit (they can transmit at any time, as AP does not sleep).

A Delivery Traffic Indication Map (DTIM) is a bit-map that

- is contained within beacons
- indicates an AP has buffered downlink traffic, and
- specifies which particular clients are awaiting transmission.

If a client has a DTIM bit set, it can retrieve data from the AP by sending a Power-Save Poll (PS-Poll) frame to the AP. This power-save scheme is effective but only allows clients to doze for a small beacon interval. Clients still need to wake up several times per second to read DTIM from the beacon frame of the AP.

Unscheduled automatic power-save delivery (U-APSD) allows a power-save client to sleep at intervals within a beacon period. AP buffers the downlink traffic until the client wakes up and requests its delivery.

> **Note**
>
> By default Target Wake Time (TWT) is disabled on the controller. To enable TWT, run the **ap dot11 {24ghz | 5ghz| 6ghz} dot11ax twt-broadcast** command.

Optimize power-saving with target wake time

TWT capable STA can either negotiate an individual TWT agreement with TWT-scheduling AP, or it can elect to be part or member of Broadcast TWT agreement existing on the AP. An STA does not need to be aware that a TWT service period can be used to exchange frames with other STAs.

Any frame exchanges that occur during a TWT service period can use any Physical Protocol Data Unit (PPDU) format that is supported by both the AP and STA involved in that TWT agreement. This includes formats such as High Efficiency Multi-User PPDU (HE MU PPDU) and High Efficiency Trigger-Based PPDU (HE TB PPDU).

The TWT agreement types are:

- **Individual TWT**: An individual TWT session is established through negotiation between the AP and a single STA. This arrangement provides a dedicated service period for both downlink and uplink communication between the AP and that specific STA. The expected traffic is highly concentrated within the negotiated service period, achieving up to 99% accuracy. Each service period begins at a defined offset from the Target Beacon Transmission Time (TBTT), lasts for the agreed-upon duration, and then repeats at regular intervals.
- **Solicited TWT**: In a solicited TWT agreement, the STA initiates the TWT session by sending a request to the AP.
- **Unsolicited TWT** : In an unsolicited TWT agreement, the AP initiates the TWT agreement with the STA. The AP sends a TWT response specifying the service period, which the STA then accepts.
- **Broadcast TWT**: In a broadcast TWT agreement, a High-Efficiency AP invites the STA to join a broadcast TWT operation, which may involve participating in an existing broadcast service period or a newly established service period.

TWT requesting STA communicates the wake scheduling information to its TWT responding AP, which then devises a schedule and delivers the TWT values to the TWT requesting STA when a TWT agreement has been established between them.

Configure target wake time at radio level (CLI)

Describes the steps to configure TWT at the radio level.

Complete this task to configure target wake time at the radio level.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable the 802.11a, 802.11b, or 802.11 6-GHz network.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} shutdown
```

3. Configure the 802.11ax parameters.

Example

```
Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} dot11ax
```

802.11ax cannot be disabled on the 6-GHz band.

4. Configure 802.11 6-GHz dot11ax target wake-up time.

Example

```
Device(config)# [no] ap dot11 {24ghz | 5ghz | 6ghz} dot11ax target-wakeup-time
```

5. Configure 802.11 6-GHz dot11ax target wake-up time broadcast.

Example

```
Device(config)# [no] ap dot11 {24ghz | 5ghz | 6ghz} dot11ax twt-broadcast
```

> **Note**
>
> By default TWT is disabled on the controller. Enable TWT by running this command.

6. Enable the 802.11a, 802.11b, or 802.11 6-GHz network.

Example

```
Device(config)# no ap dot11 {24ghz | 5ghz | 6ghz} shutdown
```

7. Display and verify the 802.11ax network configuration details, which includes information about Target Wakeup Time and Target Wakeup Broadcast.

Example

```
Device(config)# show ap dot11 {24ghz | 5ghz | 6ghz} network
```

The target wakeup time at the radio level is configured.

```
Device# configure terminal
Device(config)# ap dot11 24ghz shutdown
Device(config)# ap dot11 24ghz dot11ax
Device(config)# [no] ap dot11 24ghz dot11ax target-wakeup-time
Device(config)# [no] ap dot11 24ghz dot11ax twt-broadcast
Device(config)# no ap dot11 24ghz shutdown
```

Enable target wakeup time on WLAN (CLI)

Describes the CLI steps to enable target wakeup time on WLAN.

Complete this task to enable target wakeup time on the WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-profile-name
   ```

   The *wlan-profile-name* is the profile name of the configured WLAN.

3. Disable the WLAN network.

   Example

   ```
   Device(conf-wlan)# shutdown
   ```

4. Configure target wake time mode on WLAN.

   Example

   ```
   Device(conf-wlan)# dot11ax target-waketime
   ```

5. Configure the TWT broadcast support on WLAN.

   Example

   ```
   Device(conf-wlan)# dot11ax twt-broadcast-support
   ```

6. Enable WLAN.

   Example

   ```
   Device(conf-wlan)# no shutdown
   ```

7. Display the details of the configured WLAN, including Target Wakeup Time and Target Wakeup Broadcast Time.

   Example

   ```
   Device# show wlan {all | id | name | summary}
   ```

The target wakeup time is enabled on the WLAN.

```
Device# configure terminal
Device(config)# wlan wlan-profile-name
Device(conf-wlan)# shutdown
Device(conf-wlan)# dot11ax target-waketime
Device(conf-wlan)# dot11ax twt-broadcast-support
Device(conf-wlan)# no shutdown
```

Disable target wakeup time on WLAN (CLI)

Describes the CLI steps to disable Target Wakeup Time on the WLAN.

Complete this task to disable target wakeup time on WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-profile-name
   ```

   The *wlan-profile-name* is the profile name of the configured WLAN.

3. Disable the WLAN.

   Example

   ```
   Device(conf-wlan)# shutdown
   ```

4. Disable the target wake time mode on WLAN.

   Example

   ```
   Device(conf-wlan)# no dot11ax target-waketime
   ```

5. Disable the TWT broadcast support on WLAN.

   Example

   ```
   Device(conf-wlan)# no dot11ax twt-broadcast-support
   ```

6. Enable WLAN.

Example

```
Device(conf-wlan)# no shutdown
```

The target wakeup time is disabled on the WLAN.

```
Device# configure terminal
Device(config)# wlan wlan-profile-name
Device(conf-wlan)# shutdown
Device(conf-wlan)# no dot11ax target-waketime
Device(conf-wlan)# no dot11ax twt-broadcast-support
Device(conf-wlan)# no shutdown
```

Configure target wake time (GUI)

Configure Target Wake Time using GUI.

Complete this task to configure the target wakeup time and the broadcast for target wakeup time.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Parameters**.

   The parameters page is displayed where you can configure global parameters for 5 GHz band and 2.4 GHz band radios.

2. In the **11ax Parameters** section, check the **Target Wakeup Time** check box and the **Target Wakeup Time Broadcast** check box to configure target wakeup time and broadcast target wakeup time.

The target wakeup time and the target wakeup time broadcast are configured.

Verify target wakeup time

Verify Target Wakeup Time.

To verify Target Wakeup Time and Target Wakeup Time Broadcast, use this command

```
Device#show ap dot11 24ghz network
.
.
.
802.11ax                                : Enabled
Target Wakeup Time                      : Enabled
Target Wakeup Time Broadcast            : Enabled
.
.
.
```

57 Enabling USB Port on Access Points

Topics:

- USB port as power source for access points

The document explains how to enable and configure the USB port on Cisco Catalyst 9800 Series Access Points using both GUI and CLI methods. It details steps to enable or disable the USB module, override USB status from AP profiles, and notes specific considerations for certain AP models like the 9105AXW. This configuration allows management of USB ports for power and device connectivity on the APs.

USB port as power source for access points

Outlines the capabilities of USB ports on Access Points, guiding users through profile configuration, USB settings management via CLI and GUI, and monitoring USB configurations for optimal power usage and device integration.

A USB port as power source for access points is a power feature that

- provides up to 2.5W of power to connected USB devices
- automatically shuts down when a device draws more than 2.5W to prevent overload, and
- is available on select Cisco AP models as specified in their datasheets.

USB port power specifications

The USB port enables when the power draw is 2.5W and lower. Refer to the datasheet of your AP to check if the AP has a USB port that can act as a source of power.

Note

Both IW6300 and ESW6300 APs have a USB port that can act as a source of power up to 4.5W for some USB devices.

Note

The controller records the last five power-overdrawn incidents in its logs.

Caution

When unsupported USB device is connected to the Cisco AP, the following message is displayed:

```
The inserted USB module is not a supported device. The behavior of this USB
device and the impact to the Access Point is not guaranteed. If Cisco determines
that a fault or defect can be isolated due to the use of third-party USB modules
installed by a customer or reseller, Cisco may withhold support under warranty
or support program under contract. In the course of providing support for Cisco
networking products, the end user may be required to install Cisco-supported
USB modules in the event Cisco determines that removing third-party parts will
assist Cisco in diagnosing root cause for troubleshooting purposes. Cisco also
reserves the right to charge the customer per then-current time and material
rates for services provided to the customer when Cisco determines, after having
provided such services, that an unsupported device caused the root cause of
the defective product
```

Configure an AP profile (CLI)

Configure an AP Profile using commands.

Create and configure an AP profile to manage access point settings and behavior.

AP profiles allow you to define configuration parameters that can be applied to multiple access points, providing consistent settings and simplified management across your wireless network deployment.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

   Example

   ```
   Device(config)# ap profile xyz-ap-profile
   ```

   Note

   When you delete a named profile, the APs associated with that profile will not revert to the default profile.

3. Enable USB for each AP profile.

   Example

   ```
   Device(config-ap-profile)# usb-enable
   ```

   Note

   By default, the USB port on the AP is disabled.

   Use the **no usb-enable** command to disable USB for each AP profile.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The AP profile is now configured and can be applied to access points to manage their USB settings and other profile-specific configurations.

Configure USB settings for an access point (CLI)

Configure USB settings for an AP using commands.

Enable and manage USB functionality on access points to support connected USB devices or modules.

USB ports on access points can be used for various purposes including storage, cellular modules, or other peripheral devices. This configuration allows administrators to control USB port functionality at the individual AP level.

Procedure

---

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enable the USB port on the AP.

   Example

   ```
   Device# ap name ap-name usb-module
   ```

   Example

   ```
   Device# ap name AP44d3.xy45.69a1 usb-module
   ```

   Use the **ap name** *ap-name* **no usb-module** command to disable the USB port on the AP.

   > **Note**
   >
   > If you are using Cisco Catalyst 9105AXW AP and if you enable the USB port (.3at PoE-in), it is not possible to enable the USB PoE-out at the same time.

3. Override USB status of the AP profile and consider the local AP configuration.

   Example

   ```
   Device# ap name ap-name usb-module override
   ```

   Example

   ```
   Device# ap name AP44d3.xy45.69a1 usb-module override
   ```

Use the **ap name** *ap-name* **no usb-module override** command to override USB status of the AP and consider the AP profile configuration.

> **Note**
>
> You can configure the USB status for an AP only if you enable USB override for it.

The USB settings are now configured for the specified access point, allowing control over USB port functionality and override behavior.

Configure USB settings for an access point (GUI)

Configure USB Settings for an AP using GUI.

Before you begin

Follow these steps to configure USB settings for an access point using the GUI:

Procedure

1. Choose **Configuration > Wireless > Access Points**.
2. In the **Access Points** window, click the name of the AP.
3. In the **Edit AP** window, click the **Interfaces** tab.
4. In the **USB Settings** section, configure the **USB Module State** as either of the following:
   - **ENABLED**: Enables the USB port on the AP
   - **DISABLED**: Disables the USB port on the AP

   > **Note**
   >
   > If you are using Cisco Catalyst 9105AXW AP and if you enable the USB port (.3at PoE-in), it is not possible to enable the USB PoE-out at the same time.

5. Configure **USB Override** as either of the following:
   - **ENABLED**: Overrides USB status of the AP profile and considers the local AP configuration
   - **DISABLED**: Overrides USB status of the AP and considers the AP profile configuration

   > **Note**
   >
   > You can configure the USB status for an AP only if you enable USB override for it.

6. Click **Apply & Update to Device**.

USB configuration monitoring for access points (CLI)

Lists CLI commands to monitor USB configurations for access points.

Monitor USB configurations for access points using command-line interface commands to view inventory details, module summaries, configuration details, and status information.

- To view the inventory details of APs, use this command:

  show ap name *ap-name* **inventory**

  The following is a sample output:

```
Device# show ap name AP500F.8059.1620  inventory
NAME: AP2800    , DESCR: Cisco Aironet 2800 Series (IEEE 802.11ac) Access
Point
PID: AIR-AP2802I-D-K9  ,  VID: 01,  SN: XXX1111Y2ZZZZ2800
NAME: SanDisk    , DESCR: Cruzer Blade
PID: SanDisk  ,  SN: XXXX1110010, MaxPower: 224
```

- To view the summary of an AP module, use this command:

  show ap module summary

  This is a sample output:

```
Device# show ap module summary
AP Name               External Module       External Module PID   External
Module Description
-------------------------------------------------------------------------------------
AP500F.1111.2222      Enable                SanDisk               Cruzer
Blade
```

- To view the USB configuration details for each AP, use this command:

  show ap name *ap-name* **config general**

  This is a sample output:

```
Device# show ap name AP500F.111.2222 config general

.
.
.
USB Module Type.................................. USB Module
USB Module Status................................ Disabled
USB Module Operational State..................... Enabled
USB Override ……..... Enabled
```

- To view status of the USB module, use this command:

  show ap profile name *xyz* **detailed**

  This is a sample output:

```
Device# show ap profile name xyz detailed
USB Module               : ENABLED
```

58 Dynamic Frequency Selection

Topics:

- Dynamic frequency selection
- Zero wait dynamic frequency selection

The shorter description for the chapter on Dynamic Frequency Selection (DFS) explains how Cisco Catalyst 9800 Series Wireless Controllers detect radar signals on 5 GHz radios and automatically change channels to avoid interference, ensuring regulatory compliance and network performance. It also covers configuration steps for mesh profiles to enable radar detection and coordinated channel changes.

Dynamic frequency selection

Introduces Dynamic Frequency Selection concepts, details Channel Availability Check history and operation, and provides instructions for configuring DFS using GUI and CLI methods with verification procedures.

Dynamic Frequency Selection (DFS) is a process that

- detects radar signals on DFS-enabled 5.0-GHz (802.11a/h) radios
- automatically sets the frequency to avoid interference with radar signals, and
- ensures radios configured for use in a regulatory domain do not interfere with radar systems.

Flex DFS behavior

In normal DFS, when a radar signal is detected on any of the channels in the 40-MHz or 80-MHz bandwidth, the whole channel is blocked. With Flex DFS, if the radar signals are not detected on the secondary channel, the AP is moved to a secondary channel with a reduction in the bandwidth, usually, by half.

Feature history for channel availability check (CAC)

Lists Channel Availability Check feature history.

This table provides release and related information for features explained in this module. These features are available on all releases subsequent to the one they were introduced in, unless noted otherwise.

Table 71: Feature history for channel availability check (CAC)

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.5.1	Channel Availability Check (CAC)	When a DFS channel is selected for an AP radio, the AP radio scans the channel to check for any radar signals before transmitting any frames in the DFS frequency. This process is called Channel Availability Check (CAC).

Channel availability check

Explains the process and requirements for channel availability check on DFS channels.

A channel availability check is a DFS channel scanning process that

- scans DFS channels for radar signals before transmitting any frames in the DFS frequency
- executes before you set a DFS channel for the radio, and
- marks channels as non-available for 30 minutes if radar is detected.

Channel availability check behavior

When a DFS channel is selected for an AP radio, the AP radio scans the channel to check for any radar signals before transmitting any frames in the DFS frequency. This process is called Channel Availability Check (CAC).

> **Note**
>
> CAC is executed before you set a DFS channel for the radio.

If the AP detects that a radar is using a specific DFS channel, the AP marks the channel as non-available and excludes it from the list of available channels. This state lasts for 30 minutes after which the AP checks again to see, if the channel can be used for Wi-Fi transmissions.

> **Note**
>
> - The CAC performed during a boot process takes anywhere between 1 and 10 minutes depending on the country. This is the reason as to why the DFS channels are not available immediately when an AP reboots.
> - APs in the ETSI domain scan channels which are not supported by the controller, as the hardware has the ability to scan.

DFS verification

Lists commands to verify DFS configuration and status.

Use the following commands to verify the DFS configuration:

To display the 802.11h configuration, use the following command:

```
Device# show wireless dot11h
```

To display the auto-rF information for 802.11h configuration, use the following command:

```
Device# show ap auto-rf dot11 5ghz
```

To display the auto-rF information for a Cisco AP, use the following command:

```
Device# show ap name ap1 auto-rf dot11 5gh
```

To display the channel details for a Cisco AP, use the following command:

```
Device# show ap dot11 5ghz summary
AP Name Mac Address Slot Admin State Oper State Width Txpwr Channel
---------------------------------------------------------------------------------
pnp-ap 04eb.409e.b560 1 Enabled Up 40 *8/8 (3 dBm) (52,56)
BLDG1-9130-RACK-1568 04eb.409f.11a0 1 Disabled Down 40 4/8 (15 dBm) (100,104)#
```

> **Note**
>
> In the show command, # is added right next to the channel whenever CAC is running on an AP radio.

Zero wait dynamic frequency selection

Describes a wireless feature that eliminates service outages when access points move to DFS channels by pre-monitoring potential channels.

Zero wait dynamic frequency selection is a wireless feature that

- eliminates the 60-second to 10-minute service outage when access points move to Dynamic Frequency Selection (DFS) channels
- enables access points to pre-monitor and perform Channel Availability Check (CAC) on potential DFS channels before switching, and
- is supported only in U.S. and Europe regulatory domains.

Channel availability check process

APs monitor and perform Channel Availability Check (CAC) on a potential channel for 60 seconds when AP moves to Dynamic Frequency Selection (DFS) channels. Further, the AP ensures that there is no radar operating in the same frequency range before advertising beacons and serving clients. When the AP moves to a DFS, there is a service outage for a minute. This outage can be higher and extend up to 10 minutes.

Configure zero wait dynamic frequency selection globally

Configure Zero Wait Dynamic Frequency Selection globally using the GUI to allow APs to change to DFS without service outage.

Zero Wait DFS allows access points to change to Dynamic Frequency Selection channels without experiencing service interruption. This configuration applies globally to all access points in your network.

Follow these steps to configure Zero Wait Dynamic Frequency Selection globally:

Procedure

1. Choose **Configuration > Radio Configurations > RRM**.
2. In the **RRM** page, click the **5 GHz Band** tab.
3. Click the **DCA** tab.
4. Select the **Zero Wait DFS** check box to allow the AP to change to DFS without a service outage.
5. Click **Apply**.

Zero Wait Dynamic Frequency Selection is now enabled globally for all access points in your network.

Configure zero wait dynamic frequency selection globally (CLI)

Configure Zero Wait Dynamic Frequency Selection globally using commands.

Enable Zero Wait Dynamic Frequency Selection to improve channel availability and reduce channel change delays on 5-GHz radios.

Zero Wait Dynamic Frequency Selection optimizes radar detection and channel switching processes by allowing access points to pre-scan DFS channels. This reduces service interruption when radar is detected on the current operating channel.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the Zero Wait Dynamic Frequency Selection feature.

   Example

   ```
   Device(config)# ap dot11 5ghz rrm channel zero-wait-dfs
   ```

   By default, the feature is disabled.

   Use the **no** form of this command to disable the feature.

   > **Note**
   >
   > The Zero Wait Dynamic Frequency Selection feature is only available on a 5-GHz radio.

Zero Wait Dynamic Frequency Selection is now enabled globally, allowing 5-GHz radios to perform background DFS scanning for improved channel switching performance.

Enable zero wait dynamic frequency selection on a RF profile (GUI)

Configure Zero Wait Dynamic Frequency Selection on a RF Profile using GUI.

Enable Zero Wait Dynamic Frequency Selection to allow the AP to change to DFS without a service outage.

Before you begin

Follow these steps to enable Zero Wait Dynamic Frequency Selection on a RF Profile:

Procedure

1. Choose **Configuration > Tags & Profiles > RF/Radio**.
2. In the **RF** tab, click **Add**.

   The **Add RF Profile** page is displayed.

3. Enter the name for the RF profile.
4. From the **Radio Band** drop-down, choose the **5 GHz** band.
5. Click the **RRM** tab.

6. Click the **DCA** tab.
7. Select the **Zero Wait DFS** check box to allow the AP to change to DFS without a service outage.
8. Click **Apply to Device**.

Enable zero wait dynamic frequency selection on a RF profile (CLI)

Configure zero wait dynamic frequency selection on a RF profile using commands.

Enable the Zero Wait Dynamic Frequency Selection feature to reduce DFS channel availability delays on 5 GHz RF profiles.

Zero Wait DFS allows access points to immediately use DFS channels by pre-scanning them, eliminating the typical 60-second wait time required for DFS channel availability checks. This configuration is applied at the RF profile level to improve wireless performance and channel utilization.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a radio frequency (RF) profile and enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 5ghz rf-profile profile-name
   ```

   Example

   ```
   Device(config)# ap dot11 5ghz rf-profile test-dfs
   ```

3. Enable the Zero Wait Dynamic Frequency Selection feature for the RF profile.

   Example

   ```
   Device(config-rf-profile)# channel zero-wait-dfs
   ```

   Use the **no** form of this command to disable the feature.

Zero Wait DFS is now enabled on the RF profile, allowing access points using this profile to immediately utilize DFS channels without the standard waiting period.

Zero wait dynamic frequency selection configuration verification

Lists commands to verify Zero Wait Dynamic Frequency Selection configuration.

Use the following commands to verify the DFS configuration.

To display the Zero Wait DFS configuration on an AP, use the following command:

```
Device# show ap name ap1 config slot 1 | inc Zero

  Zero Wait DFS Parameters
    Zero Wait DFS Capable                        : Yes
    CAC Domain                                   : None
```

To display the global configuration related to the Zero Wait Dynamic Frequency Selection feature, use the following command:

```
Device# show ap dot11 5ghz channel | inc Zero

  Zero Wait DFS Parameters
    Zero Wait DFS Capable                        : Yes
    CAC Domain                                   : None
```

To display the RF profile configuration related to the Zero Wait Dynamic Frequency Selection feature, use the following command:

```
Device# show ap rf-profile name test detail | sec Zero

Description                          :
RF Profile Name                      : test
Band                                 : 5 GHz
Transmit Power Threshold v1          : -70 dBm
Min Transmit Power                   : -10 dBm
Max Transmit Power                   : 30 dBm
.
.
.
Guard Interval                       : default
Zero Wait DFS                        : Enabled
```

59 Cisco Access Points with Tri-Radio

Topics:

- Cisco access points with tri-radio

The document describes the Tri-Radio feature for Cisco Access Points, detailing how three radios operate to optimize performance in high-density environments. It explains radio roles, dual radio mode configurations, and provides guidelines and procedures for managing Tri-Radio settings on Cisco Catalyst 9800 Series Wireless Controllers.

Cisco access points with tri-radio

Describes Cisco APs with tri-radio capabilities and their operational modes for high density environments.

A Cisco access point with tri-radio is a wireless device that

- operates three radios designed for high density environments
- runs one dedicated 2.4-GHz 4x4 mode radio and one 5-GHz 8x8 mode radio by default, and
- enables the 8x8 radio to split into two independent 5-GHz 4x4 radios when dual radio mode is enabled.

Tri-radio operational modes and configuration

Access Points with three radios are designed for high density environments. The APs by default run one dedicated 2.4-GHz 4x4 mode radio and one 5-GHz 8x8 mode radio. In the default mode, the radios are managed by the Flexible Radio Assignment (FRA), and the Dual Radio Mode is in the disabled state indicating that the radios have either been assigned as client serving 8x8 radio or have not yet been evaluated by FRA.

When you enable the dual radio mode setting, the 8x8 radio is split to two independent 5-GHz 4x4 radios. In this mode, slot 1 and slot 2 are active independent 4x4 radio interfaces. They can serve different user groups with different assigned channels.

> **Note**
>
> To disable the dual radio mode, you must first disable the admin status of the subordinate radio. Otherwise, a warning message is displayed.

In Cisco IOS XE Dublin 17.13.1, the **ap tri-radio** command cannot be configured, since the Tri-radio settings are enabled by default, and cannot be disabled.

A tri-radio AP has upto two configurable 5-GHz radios. The following table describes the radio role and its deployment benefits:

Table 72: 5-GHz radio operational modes and criteria

Radio Role		Driving Factors
Radio 1	**Radio 2**	
8x8 Client-Serving	None	• Preferred operation: 160 MHz or 80 + 80 MHz • Higher MU-MIMO stations • Required higher number of Spatial Streams (SS)
4x4 Client-Serving	4x4 Client-Serving	• Preferred operation: 80 MHz or below • High Capacity in low or medium density • Directional antenna units (Coverage Slicing)

Radio Role		Driving Factors
Radio 1	**Radio 2**	
4x4 Client-Serving	4x4 Monitor	• Preferred operation: 80 MHz or below • Lower MU-MIMO stations • Better channel reuse in high density • Monitoring application requires 4x4 Rx

The following table lists the different radio modes and roles supported by the AP:

Table 73: Tri-radio AP radio configuration

Setup	Radio Mode	Maximum Radio Capability	Dual Role Mode
1	2.4-GHz + 5-GHz	2.4-GHz, 4 antennas, 4SS, and 20 MHz 5-GHz, 8 antennas, 4SS, and 160 MHz	Disabled
2	5-GHz + 5-GHz	2.4-GHz, 4 antennas, 4SS, and 20 MHz 5-GHz, 4 antennas, 4SS, and 80 MHz 5-GHz, 4 antennas, 4SS, and 80 MHz	Enabled

In the Cisco IOS XE 17.2.1 Release, FRA manages the role assignment for each radio independently. You can set the radio mode as automatic or manual, and select either Client-Serving role or Monitor role as the radio role. Based on the dual radio mode configuration, the role selection is available for one or for both interfaces.

Guidelines and restrictions for tri-radio access points

Outlines configuration guidelines and hardware restrictions for tri-radio access point deployment and management.

- Dual radio mode is set to **Auto** by default. FRA manages the dual radio mode in **Auto** mode.
- The tri-radio support for AP with external antenna is as follows:
  - RP-TNC antenna is supported in Cisco Catalyst 9130AX Series APs.
  - The C-ANT9101, C-ANT9102, and C-ANT9103 antennas on Cisco Catalyst 9130AX Series APs support 2 radios (2.4-GHz (4x4) and 5-GHz (8x8)). This antennas does not support two 5-GHz (4x4) radios due to hardware limitation.
- From Cisco IOS XE Cupertino 17.7.x, the Tri-Radio feature is supported in Cisco Catalyst 9124 Series APs.

Configure tri-radio for AP (GUI)

Configure Tri-Radio for AP using GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Network**.

   The **Network** > **5 GHz Radios** page is displayed.

2. In the **General** tab, the **Tri-Radio Mode** check box is enabled by default. Check the check box to enable this feature.

   > **Note**
   >
   > Enabling the check box will allow Tri-Radio Mode for all APs capable of this feature. If you disable this later, the affected APs will revert to their default radio configuration.

3. Click **Apply**

Configure the tri-radio (CLI)

Configure the tri-radio using commands.

Enable tri-radio functionality on supporting access points to optimize wireless performance through automatic dual radio role management.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure all supporting tri-radio AP's dual radio role in auto mode.

   Example

   ```
   Device(config)# [no] ap tri-radio
   ```

   Use the **[no]** form of the command to disable the feature.

The tri-radio feature is configured on all supporting access points, enabling automatic dual radio role management for optimized wireless performance.

Configure 5-GHz dual radio mode for AP (GUI)

Configure 5-GHz dual radio mode for AP using GUI.

Before you begin

Follow these steps to configure 5-GHz dual radio mode for AP using GUI:

Procedure

1. Choose **Configuration** > **Wireless** > **Access Points**.
2. On the **Access Points** page, click the **5 GHz Radios** section and select a Cisco 9130 Series AP from the list.

   The **Edit Radios 5 GHz Band** window is displayed.
3. In the **Edit Radios 5-GHz Band** > **Configure** > **General** tab, under **Dual Radio Mode**, select one from the following radio button options
   - Auto: Permits FRA to decide the mode for this AP.
   - Enabled: Enables Dual Radio mode for this AP.
   - Disabled: Disables Dual Radio mode for this AP.
4. Click **Update & Apply to Device**.

Configure the dual radio mode and enable slots (CLI)

Configure the dual radio mode and enable slots using commands.

Configure dual radio mode on Cisco APs to enable flexible radio operation and optimize wireless coverage.

Dual radio mode allows Cisco APs to operate with enhanced radio flexibility, supporting both dual and tri-radio configurations. This is useful for environments requiring optimized wireless performance and coverage management.

Procedure

1. Optional: Disable the 802.11a radio on Cisco AP.

   Example

   ```
   Device# ap name ap-name dot11 5ghz slot slot-number shutdown
   ```

   Example

   ```
   Device# ap name ap-name dot11 5ghz slot 1 shutdown
   ```

   Disables the 802.11a radio on Cisco AP.
2. Configure the 802.11a dual and tri-radio on the AP.

   Example

   ```
   Device# ap name ap-name dot11 5ghz slot 1 dual-radio mode mode-option
   ```

   Example

   ```
   Device# ap name ap-name dot11 5ghz slot 1 dual-radio mode enable
   ```

Configures the 802.11a dual and tri-radio on the AP. Enable auto to allow RRM to switch the AP between dual radio or tri radio mode based on the channel width configuration. In auto mode, the slot 2 state is managed by the RRM. Use the disable keyword to disable the dual-radio.

> **Note**
>
> When the AP is set to auto mode, the dual radio mode is disabled by default.

3. Enable the 802.11a radio on Cisco AP.

Example

```
Device# ap name ap-name no dot11 5ghz slot slot-number shutdown
```

Example

```
Device# ap name ap-name no dot11 5ghz slot 1 shutdown
```

Enables the 802.11a radio on Cisco AP.

The dual radio mode is configured and the specified slots are enabled, allowing the AP to operate with the configured radio settings.

Set radio roles for slots (CLI)

Configure radio roles for slots using commands.

Before you begin

Follow these steps to set radio roles for slots using CLI commands:

> **Note**
>
> Radio role assignment is supported only for access points operating in local mode. It is not supported for access points operating in bridge mode.

Procedure

---

1. **enable**

Example

```
Device> enable
```

Enables privileged EXEC mode.

Enter your password, if prompted.

2. **ap name** *ap-name* **dot11 24ghz 5ghz | 6ghz slot** *<slot ID>* **radio role auto manual monitor client-serving**

Example

```
Device# ap name ap-name dot11 5ghz slot 2 radio role manual monitor
```

Sets the radio role manual to either client serving or monitor.

Configure the tri-radio dual radio role (CLI)

Configure the tri-radio dual radio role using commands.

Set up tri-radio dual radio role configuration to optimize wireless coverage and monitoring capabilities.

Tri-radio access points support independent radio role configuration for each radio, allowing you to designate radios for client-serving or monitoring functions to optimize network performance and security.

Procedure

1. Configure the 802.11a radio role independently for each supporting AP's radio.

   Example

   ```
   Device# ap name ap-name dot11 5ghz slot slot-number radio role role-mode
   function
   ```

   Example

   ```
   Device# ap name 9130axtrial dot11 5ghz slot 1 radio role manual monitor
   ```

   The channel and the Tx power values can be configured when the radio role is set to manual mode.

2. Configure the 802.11b radio role independently for the supporting AP's radio.

   Example

   ```
   Device# ap name ap-name dot11 24ghz slot 0 radio role role-mode function
   ```

   Example

   ```
   Device# ap name 9130axtrial dot11 24ghz slot 0 radio role manual client-serving
   ```

The tri-radio dual radio roles are configured, with each radio optimized for its designated function of either client-serving or monitoring.

Tri-radio configuration verification on the controller

Lists commands to verify tri-radio configuration on the controller.

To verify that the dual radio mode is enabled, use the following **show** command:

```
Device# show ap name APXXXX.4XXX.04XX config slot 1 | inc Dual
 Dual Radio Capable                              : True
 Dual Radio Mode                                 : Enabled
 Dual Radio Operation mode                       : Auto
```

To verify the tri-radio status, use the following **show** command:

```
Device# show ap triradio status
Tri-Radio Status : Enabled
```

To verify that the radio role is set, use the following **show** command:

```
show ap name ap-name config slot <slot_number> | i Radio
Radio Type                                     : 802.11ax - 5 GHz
Radio Subband                                  : All
Radio Role                                     : Auto
Radio Mode                                     : Local
Radio SubType                                  : Main
```

60 Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard

Topics:

- Cisco Catalyst Center assurance Wi-Fi 6 dashboard

The Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard provides a visual overview of your wireless network's Wi-Fi 6 readiness and performance. It features dashlets that display client distribution by capability, AP readiness, protocol distribution, airtime efficiency, and wireless latency comparisons between Wi-Fi 6 and non-Wi-Fi 6 networks, helping to assess and optimize network efficiency and client experience. Configuration and verification procedures are available via CLI for debugging purposes, though management is recommended through the Cisco Catalyst Center.

Cisco Catalyst Center assurance Wi-Fi 6 dashboard

Explains the Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard that provides a visual representation of your wireless network.

The Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard is a visual interface that

- provides a comprehensive view of your wireless network performance and capabilities
- displays various dashlets showing Wi-Fi 6 readiness and network efficiency comparisons, and
- enables monitoring of Wi-Fi 6 networks compared to non-Wi-Fi 6 networks.

Dashboard components

> **Note**
>
> We recommend you manage this feature using the Cisco Catalyst Center UI. The procedures are to be executed with for debugging purposes only.

The dashboard contains the following dashlets:

- **Client Distribution by Capability**: This dashlet shows all the clients associated and their capability in the wireless network. The inner circle shows the wireless protocol capabilities of all the different clients in the network. Capability here is the ability of wireless clients to associate with Wi-Fi 6 APs or non-Wi-fi 6 APs. The outer arc segment shows how many 802.11ax capable clients are joined to a Wi-Fi 6 network as well as how many of them are not.
- **Wi-Fi 6 Network Readiness**: This dashlet shows all the APs in the network. The inner circle shows the APs which are Wi-Fi 6 APs and non Wi-Fi 6 APs. The outer arc segment shows the number of Wi-Fi 6 enabled AP in the network.
- **AP Distribution by Protocol**: This dashlet shows the protocols enabled on your APs in real time.
- **Wireless Airtime Efficiency**: This dashlet compares and displays the Airtime Efficiency between your Wi-Fi 6 network and Non-Wi-Fi 6 network for each of the access categories (voice, video, best effort, background).

  The spectrum is efficiently utilized if the AP's radios can send more traffic (successful bytes transmitted to the client) in less airtime (microseconds) than other networks under similar RF conditions.
- **Wireless Latency by Client Count**: This Dashlet compares the Wireless Latency between your Wi-Fi 6 and Non-Wi-Fi 6 Network for each of the access categories (voice, video, best effort, background).

  Wireless latency is measured by the time (microseconds) it takes for a packet to be successfully transmitted from an AP to the client. Hence, AP radios with a higher client count generally have higher latency than compared to those with a lower client count under similar RF conditions.

  > **Note**
  >
  > **Client count** in this dashlet refers to the clients that are actively sending traffic for a given Access Category and are not just associated clients.

For more information, see the **Monitor Wi-Fi 6 Readiness** section in the Cisco DNA Assurance User Guide.

Configure Cisco Catalyst Center assurance Wi-Fi 6 dashboard parameters (CLI)

Configure Cisco Catalyst Center Assurance Wi-Fi 6 Dashboard Parameters using commands.

Enable and configure traffic distribution statistics collection for Wi-Fi 6 dashboard monitoring in Cisco Catalyst Center Assurance.

The traffic distribution feature provides detailed analytics about wireless network performance, including signal strength distribution, airtime efficiency by access category and traffic type, and latency metrics. This data is essential for Wi-Fi 6 network optimization and troubleshooting through the Cisco Catalyst Center dashboard.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable configuration for all the APs that are associated with the specified AP profile name.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

   Example

   ```
   Device(config)# ap profile pp-1
   ```

3. Enable traffic distribution feature with the specified AP profile.

   Example

   ```
   Device(config-ap-profile)# statistics traffic-distribution
   ```

4. Configure the interval at which the AP sends the traffic distribution statistics.

   Example

   ```
   Device(config-ap-profile)# statistics traffic-distribution interval
   interval-secs
   ```

   Example

   ```
   Device(config-ap-profile)# statistics traffic-distribution interval 300
   ```

   Default value is 300 seconds. Valid range is between 30 and 3600 seconds.

> **Note**
>
> Execute this command only with the assistance from Cisco Technical Assistance Center (TAC) support engineer.

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-profile)# exit
   ```

6. Display traffic distribution data by signal strength, if received from the AP in the latest statistics update interval.

   Example

   ```
   Device# show wireless stats ap name ap-name traffic-distribution slot slot-id
    packet-count signal {average | good | poor} [last-received]
   ```

   Example

   ```
   Device# show wireless stats ap name ff123a traffic-distribution slot 1
   packet-count signal good
   ```

   Use **last-received** keyword to view the statistics received in any statistics update interval from the AP.

7. Display the Airtime efficiency data based on access category, if received from the AP in the latest statistics update interval.

   Example

   ```
   Device# show wireless stats ap name ap-name traffic-distribution slot slot-id
    airtime access-category {background | best-effort | video | voice}
   [last-received]
   ```

   Example

   ```
   Device# show wireless stats ap name ff123a traffic-distribution slot 1 airtime
    access-category best-effort
   ```

   Use **last-received** keyword to view the statistics received in any statistics update interval from the AP.

8. Display the Airtime efficiency data based on traffic type, if received from the AP in the latest statistics update interval.

   Example

   ```
   Device# show wireless stats ap name ap-name traffic-distribution slot slot-id
    airtime traffic-type {legacy | mu | ofdma | su} [last-received]
   ```

   Example

   ```
   Device# show wireless stats ap name ff123a traffic-distribution slot 1
   traffic-type ofdma
   ```

Use **last-received** keyword to view the statistics received in any statistics update interval from the AP.

9. Display wireless latency data based on access category, if received from the AP in the latest statistics update interval.

Example

```
Device# show wireless stats ap name ap-name traffic-distribution slot slot-id
 latency access-category {background | best-effort | video | voice}
[last-received]
```

Example

```
Device# show wireless stats ap name ff123a traffic-distribution slot 1 latency
 access-category best-effort
```

Use **last-received** keyword to view the statistics received in any statistics update interval from the AP.

Traffic distribution statistics are now enabled and configured for the specified AP profile, allowing Cisco Catalyst Center Assurance to collect and display Wi-Fi 6 dashboard analytics including signal strength distribution, airtime efficiency, and latency metrics.

AP DFS counter verification (CLI)

Lists commands to verify AP DFS counters using CLI commands.

Verify AP DFS counters using CLI commands for selected radio bands and specific access points.

DFS counter verification commands

- To verify the DFS counter for the selected radio band:

  show ap auto-rf dot11 24ghz | 5ghz | dual-band

```
Device#show ap auto-rf dot11 dual-band
```

- To verify the DFS counter for the selected radio band of a specific AP:

  show ap name *ap-name* **auto-rf dot11 24ghz | dual-band**

```
Device#show ap name ff32a auto-rf dot11 dual-band
```

- To verify the DFS counter for the selected 5-GHz slot of a specific AP:

  show ap name *ap-name* **auto-rf dot11 5ghz slot** *slot-id*

```
Device#show ap name ff32a auto-rf dot11 5ghz slot 1
```

Wi-Fi 6 access point parameter verification

Lists commands to verify Wi-Fi 6 access point parameters in the AP console and Cisco Catalyst 9800 Wireless Controller console.

Enter these commands in the AP console.

- To verify the traffic distribution statistics configuration, use the following command: **show ap traffic distribution configuration**

- To verify the exported data from the AP to the controller, use the following command: **show interfaces dot11Radio** *slot-id* **traffic distribution** {**cumulative** | **instantaneous** | **periodic**} **database**
- To verify Access Point DFS counters, use the following command: **show interfaces dot11radio** *slot-id***dfs**
- To debug the traffic distribution statistics, use the following command: {**no**} **debug traffic wireless distribution dump** {**periodic** | **aggregated**}
- To clear the traffic distribution dump, use the following command: **clear traffic distribution dump**

61 Antenna Disconnection Detection

Topics:

- Antenna disconnection detection

Antenna disconnection detection

Introduces antenna disconnection detection, detailing recommendations and limitations, operational mechanisms, configuration for CLI and GUI, SNMP trap detection processes, and verification procedures for confirming antenna status and setup integrity.

The Antenna Disconnection Detection feature monitors the signal strength across antennas on a receiver.

- Having multiple antennas on both transmitters and receivers enhances performance and reliability of APs
- Multiple antennas offer better reception by choosing the stronger signal or combining signals
- Detecting impaired antennas or physical damage is crucial for AP reliability

Whenever the signal strength delta goes beyond a set limit for a certain period, the antenna is likely experiencing issues.

For every detection time period that you configure, the AP sends an Inter-Access Point Protocol (IAPP) message that carries the antenna condition. This message is sent only once when the issue is detected and is displayed in the controller trap messages, SNMP traps, and controller debug logs.

Feature History

Release	Feature	Feature Information
Cisco IOS XE Bengaluru 17.4.1	Antenna Disconnection Detection	This feature detects the signal strength delta across the antennas on the receiver. If the delta is more than the defined limit for a specific duration, the corresponding antenna is considered to have issues.

Supported APs

The feature is supported only on these APs

- Cisco Catalyst 9120AX Series Access Points
- Cisco Catalyst 9130AX Series Access Points
- Cisco Aironet 2800e Access Points
- Cisco Aironet 3800e Access Points

Configuration workflow

1. Configure APs.
2. Configure an AP profile.
3. Enable the feature in AP profile.
4. Configure feature parameters.
5. Verify the configuration.

Limitations

Limitations of antenna disconnection detection for specific APs.

This document outlines limitations for specific APs.

- The SNMP trap is not supported on the Cisco Embedded Wireless Controller.
- The IAPP message is sent only when there is a change in the error condition.

How antenna disconnection detection works

Summary

The antenna disconnection detection process monitors signal strength across antennas and identifies malfunctioning antennas based on relative and absolute RSSI thresholds. It improves access point reliability by flagging weak or failed antennas early.

The key components involved in the process are

- Access point (AP): Compares RSSI values of all antennas and monitors for signal anomalies.
- RSSI thresholds: Include both relative (RSSI failure threshold) and absolute (weak RSSI) values.
- Detection timer: Sets the evaluation duration before confirming a disconnection.
- IAPP messaging: Sends a one-time alert when a disconnection is detected.

Workflow

The process involves these stages

1. Signal monitoring: The AP measures the received signal strength (RSSI) of all antennas.
2. Relative comparison: Each antenna's RSSI is compared to the antenna with the highest RSSI. If the delta exceeds the RSSI failure threshold, that antenna is marked as broken.
3. Absolute check: If all antennas have RSSI values below the weak RSSI threshold, they are all marked as malfunctioning, regardless of delta comparison.
4. Failure fallback: If neither condition is satisfied (e.g., threshold not met), the system defaults to reporting all antennas as malfunctioning.
5. Alert transmission: When a failure condition is confirmed, an IAPP message is generated once to notify monitoring systems via controller logs, SNMP traps, or debug logs.

Result

This process ensures reliable antenna monitoring by combining relative and absolute RSSI evaluations, resulting in faster detection of signal degradation and hardware faults.

Configure antenna disconnection detection

Configuring antenna disconnection detection using commands.

Enable antenna disconnection detection via CLI to monitor and alert on failing antennas.

This task applies to compatible Cisco access points. It uses RSSI thresholds and detection timers to identify and alert on signal anomalies that may indicate hardware failure.

Before you begin

Identify the AP profile to configure.

Procedure

1. Enter global configuration mode

Example

```
Device# configure terminal
```

Enters global configuration mode.

2. Configure an AP profile and enter AP profile configuration mode

Example

```
Device(config)# ap profile xyz-ap-profile
```

Configures an AP profile and enters AP profile configuration mode.

3. Enable antenna disconnection detection

Example

```
Device(config-ap-profile)# antenna monitoring
```

Enables antenna disconnection detection.

To disable antenna disconnection detection, use the **no antenna monitoring** command.

4. Configure RSSI failure threshold value

Example

```
Device(config-ap-profile)# antenna monitoring rssi-failure-threshold 20
```

Configures RSSI failure threshold value, in dB. Valid values range from 10 to 90, with a default of 40.

5. Configures weak RSSI value

Example

```
Device(config-ap-profile)# antenna monitoring weak-rssi -90
```

Configures weak RSSI value, in dBm. Valid values range from -90 to -10, with a default of 60.

6. Configure the antenna disconnection detection time

Example

```
Device(config-ap-profile)# antenna monitoring detection-time 20
```

Configures the antenna disconnection detection time, in minutes. Valid values range from 9 to 180, with a default of 120.

7. Return to privileged EXEC mode

Example

```
Device(config-ap-profile)# end
```

Saves the configuration and returns to privileged EXEC mode.

The network device actively monitors the antenna disconnection status and detect malfunctioning antennas based on configured RSSI thresholds. This enables timely alerts and corrective actions to maintain optimal network performance.

Configure antenna disconnection detection using GUI

Configure antenna disconnection detection using GUI.

Enable and configure antenna disconnection detection using the GUI.

Procedure

---

1. Choose **Configuration > Tags & Profiles > AP Join**.
2. In the **AP Join Profile** window, click the **General** tab.
3. Check the **Antenna Monitoring** check box to enable antenna monitoring.
4. In the **RSSI Fail Threshold(dB)** field, enter a value, in dB. The values range from 10 to 90 dB, with a default of 40.
5. In the **Weak RSSI(dBm)** field, enter a value, in dBm. Valid values range from -90 to -10 dBm, with a default of 60 dBm.
6. In the **Detection Time(min)** field, enter the antenna disconnection detection time, in minutes. Values range from 9 to 180 min, with a default of 120 min.
7. Click **Update & Apply to Device**.

The system applies the antenna disconnection detection settings to the device according to your specifications.

Detect broken antenna using SNMP trap (CLI)

Detect broken antenna using SNMP trap using commands.

Configure SNMP traps for antenna failures to enable rapid detection and response to hardware issues in APs.

Procedure

---

1. Enter global configuration mode

   Example

   ```
   Device# configure terminal
   ```

   Enters global configuration mode.

2. Enable all SNMP notification types

   Example

   ```
   Device(config)# snmp-server enable traps
   ```

   Enables all the SNMP notification types that are available on the system.

3. Configure SNMP trap for broken antenna detection

Example

```
Device(config)# trapflags ap broken-antenna
```

Enables an SNMP trap, which sends notifications when an antenna fails in any Cisco AP.

4. Return to privileged EXEC mode

Example

```
Device(config)# end
```

Returns to privileged EXEC mode.

SNMP trap notifications is sent when an antenna failure is detected, facilitating prompt maintenance actions.

Detect broken antenna using SNMP trap (GUI)

Detect broken antenna using SNMP trap using GUI.

Detect and report issues with antenna performance automatically using SNMP traps.

Procedure

---

1. Choose **Administration > Management > SNMP**.
2. Click the **Wireless Traps** tab.
3. Set the **Access Point** status as **Enabled**, if not done already.
4. Check the **Broken Antenna** check box to enable the trap.
5. Click **Apply**.

The system monitors antenna statuses and generates SNMP traps for any malfunctions, promptly notifying administrators to facilitate quick resolution and improve network reliability.

Verify antenna disconnection detection (Reference)

To verify the antenna disconnection detection feature configuration on an AP and AP profile.

You must ensure that the antenna disconnection detection feature is configured accurately on both individual access points and their profiles. This involves verifying specific settings like RSSI thresholds and detection times to maintain optimal network performance.

To verify the antenna disconnection detection feature configuration on an AP, use the following command:

```
Device# show ap name 3800-AP config general

Cisco AP Name: 3800-AP
================================================

Cisco AP Identifier                              : f4db.e632.df40

To verify the antenna disconnection detection feature configuration on an AP profile, use the following command:

```
Device# show ap profile name rf-profile-24g detailed

AP Profile Name: rf-profile-24g
.
.
.
AP broken antenna detection:
  Status                                                    : ENABLED
  RSSI threshold                                            : 40
  Weak RSSI                                                 : -80
  Detection Time                                            : 120
```

Verify antenna disconnection detection (GUI)

Verify antenna disconnection detection using GUI.

User can verify whether the antenna disconnection detection is supported by the access points, ensuring the system's monitoring capabilities are accurate and reliable.

Procedure

1. Choose **Monitoring > Wireless > AP Statistics**.
2. Click an AP name or anywhere on the row corresponding to an AP to activate the **General** window.
3. Click the **360 View** tab.

   The 360 View tab is the default selection. The **Antenna Monitoring** field indicates whether the AP supports monitoring or not.

Verify that the Antenna Monitoring field indicates support status. If supported, monitoring is accurate and reliable.

62 Neighbor Discovery Protocol Mode on Access Points

Topics:

- NDP mode
- Configuration Tasks

NDP mode

Introduces Neighbor Discovery Protocol Mode, explaining its purpose, operational principles, and significance in access point deployments within wireless networks.

Neighbor Discovery Protocol (NDP) modes are wireless protocol configurations in AP that

- determine whether NDP packets are transmitted **on the serving radio's configured channel (On-Channel)** or using the **legacy Off-Channel** method where the serving radio re-tunes to other channels to transmit NDP.
- allow selection through a controller setting (**Auto** or **Off-Channel**) to match specific deployment requirements.
- support mixed (brownfield) deployments where APs with and without scanning radios coexist, automatically choosing the appropriate mode for optimal performance.

Feature history

Feature Name	Release	Description
Neighbor Discovery Protocol Mode on Cisco Catalyst 9124AX Outdoor Access Points	Cisco IOS XE 17.5.1	From this release, supported APs can operate on both on-channel and off-channel NDP modes. The feature is configured per slot: • **ap dot11 {24ghz | 5ghz} rrm ndp-mode {auto | off-channel}** • **ndp-mode {auto | off-channel}**

Supported radios

- Cisco Aironet 3800 Series (Wi-Fi 5 with scanning radio; 2.4 GHz or 5 GHz only)
- Cisco Catalyst 9120 Series Access Points
- Cisco Catalyst 9130 Series Access Points
- Cisco Catalyst 9124 Series Access Points
- All Wi-Fi 6 and newer Catalyst APs

NDP transmission modes

In outdoor deployments – and in all modern Cisco Wi-Fi 6 and newer APs – NDP packets are transmitted based on the configured Neighbor Discovery Protocol (NDP) mode, which can be set through the controller to suit deployment requirements.

- **On-Channel**- The serving (client-facing) radio remains on its configured channel and continuously streams NDP packets (about every 20 ms) only on that channel. A *full-time scanning radio* (implemented through RF ASIC or equivalent) handles all receive operations across all channels.
- **Off-Channel (Legacy)** - Used when a scanning radio is not present. The serving radio periodically re-tunes off its serving channel to transmit NDP packets on other channels, cycling through all regulatory domain channels in about three minutes. This was the standard behavior in older APs before scanning radios became available.
- Auto Mode - **Default** setting. The controller automatically selects the transmission method:
  - If **all APs have scanning radios**: uses On-Channel mode for optimal performance.

- If **any AP lacks a scanning radio**: uses Off-Channel mode for compatibility.

You can verify which mode is in use with a packet capture on any serving channel:

- If **On-Channel** is in use, NDP packets appears on that channel at approximately 20 ms intervals as a continuous stream.
- If **Off-Channel** is in use, NDP packets appears on each channel only once during a full scan cycle (about every 3 minutes for all channels combined).

Operational guidelines

- In greenfield Wi-Fi 6+ deployments, which includes all modern APs, On-Channel mode provides the best performance and neighbor acquisition times.
- In brownfield (mixed) environments, Auto setting ensures the correct mode is chosen and maintains compatibility with legacy devices.
- 6 GHz deployments always operate in **On-Channel** mode (no legacy APs exist for this band).

> **Note**
>
> The performance gain by using **On-Channel** NDP is 25% more than the performance over legacy AP's in 5 and 6 GHz. Legacy APs are Cisco APs that do not have a full-time scanning radio (RF ASIC or equivalent) and do not support 6 GHz.

Configuration Tasks

Details configuration and monitoring procedures for NDP Mode, including step-by-step instructions for GUI and CLI setup, RF profile integration, monitoring radio statistics, and verification to ensure correct NDP operation on access points.

Configure RRM NDP mode (GUI)

Configure RRM Neighbor Discovery Mode using GUI.

Set the Radio Resource Management (RRM) neighbor discovery mode for APs. This optimizes wireless network performance.

Use this task to select how access points detect neighbors—either automatically or using off-channel scanning—through the GUI.

Before you begin

Confirm that the radio you want to configure (2.4 GHz or 5 GHz) is enabled.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **RRM**.
2. In the **Radio Resource Management** window, click either the **5 GHz Band** or the **2.4 GHz Band** tab.
3. In the **General** tab, under the **Noise/Interference/Rogue/CleanAir/SI Monitoring Channels** section, click the **RRM Neighbor Discovery Mode** toggle button to configure a mode.
4. Click **Apply**.

The RRM neighbor discovery mode is updated for the selected band.

Configure the NDP mode (CLI)

Configure the NDP Mode using commands.

Set the neighbor discovery protocol (NDP) mode for 802.11 radios using CLI.

Specify whether supported APs transmit NDP packets in auto or off-channel mode for 802.11a/b/g/n/ac radios.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the operating mode for 802.11a neighbor discovery using **ap dot11 { 24ghz | 5ghz } rrm ndp-mode {auto | off-channel}** command.

   Example
   For Brownfield (mixed) deployments:

   ```
   Device(config)# ap dot11 24ghz rrm ndp-mode auto
   ```

   ```
   Device(config)# ap dot11 5ghz rrm ndp-mode auto
   ```

   Example
   Greenfield (all APs with RF ASIC conventional radios)

   ```
   Device(config)# ap dot11 24ghz rrm ndp-mode off-channel
   ```

You have configured the NDP mode.

Configure the NDP Type (CLI)

Configure the Neighbor Discovery Protocol Type using commands.

Set which type of Neighbor Discovery Protocol (NDP) messages your AP broadcasts on the selected radio band: 2.4 GHz, 5 GHz, or 6 GHz.

Use this procedure to specify whether NDP messages are **protected** or **transparent** when configuring Radio Resource Management (RRM) parameters for an AP through the CLI.

Before you begin

- Determine which radio (2.4 GHz, 5 GHz, or 6 GHz) you intend to configure.
- Determine if you want your NDP messages to be **protected** or **transparent**.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the NDP type for 802.11a (2.4 GHz), 802.11b (5 GHz), or 802.11 (6 GHz) neighbor discovery using the **ap dot11 { 24ghz | 5ghz | 6ghz } rrm ndp-type { protected | transparent }** command.

   Example

   ```
   Device(config)# ap dot11 6ghz rrm ndp-type protected
   ```

   The two types are protected and transparent.

The AP uses the designated NDP type for neighbor discovery on the specified radio band.

Configure NDP mode in the RF profile (GUI)

Enable or modify Neighbor Discovery Protocol (NDP) mode settings for a specific RF profile to optimize wireless network performance.

NDP mode affects how devices discover neighboring APs within a wireless network RF profile. You can set NDP to **Auto** or **Off-Channel** as needed.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF**.
2. Click **Add**.
   The **Add RF Profile** window is displayed.
3. Click the **General** tab.
4. Click the **NDP Mode** toggle button to select the NDP mode as **AUTO** or as **OFF-CHANNEL**.
5. Click **Apply to Device**.

The chosen RF profile is updated with the selected NDP mode setting, which is now active in your wireless environment.

Configure NDP mode in the RF profile (CLI)

Configure Neighbor Discovery Protocol Mode in the RF Profile using commands.

Set the operating mode for Neighbor Discovery Protocol (NDP) in a specified RF profile using the CLI.

Use this task to configure the NDP operating mode—either **auto** or **off-channel**—for a specific RF profile (2.4 GHz, 5 GHz, or 6 GHz) on your wireless device.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enter the RF profile configuration using the **ap dot11 { 24ghz | 5ghz| 6ghz } rf-profile** *rf-profile-name* command.

Example

```
Device(config)# ap dot11 24ghz rf-profile rf-profile-name
```

3. Configure the operating mode for neighbor discovery.

Example

```
Device(config-rf-profile)# ndp-mode mode
```

The RF profile is updated to use the specified NDP mode on the selected radio band.

Monitor radio statistics and NDP using GUI

View and analyze radio statistics, including NDP capability and mode for APs.

Use this task when you need to check and evaluate the wireless radio status and NDP settings for access points in your network environment.

Note

You can verify which NDP transmission mode is in use with a packet capture on the serving channel:

- If the AP is using **On-Channel** mode, NDP frames will appear on the serving channel at approximately 20 ms intervals as a continuous stream.
- If the AP is using **Off-Channel (legacy)** mode, NDP frames will appear on each channel only once during a full scan cycle (about every 3 minutes for all channels combined). In this case, you may not see NDP frames on the serving channel for long periods while the serving radio is tuned elsewhere.

.

Procedure

1. Choose **Monitoring** > **Wireless** > **Radio Statistics**.
2. Click either **5 GHz Radios**, **2.4 GHz Radios**, or **Dual-Band Radios** tab.
   The corresponding radio band window displays the list of configured APs.
3. To view the general attributes of an AP, click the corresponding AP to display the **General** tab. The following information is displayed:
   - **AP Name**: Displays the assigned identifier for the AP, which is unique within the network. The AP name can be ASCII characters from 32 to 126, excluding leading and trailing spaces.
   - **IP Address**: Displays the IP address assigned to the AP in dotted-decimal format.

- **AP Mode**: Displays the configured AP mode. The supported modes are:
  - **Local**: It is the default mode, and it offers a basic service set (BSS) on a specific channel. When the AP does not transmit wireless client frame, it scans other channels to measure noise interference, discover rogue devices, and check for matches against Intrusion Detection System (IDS) events.
  - **Monitor**: An AP in monitor mode does not transmit. It is a dedicated sensor that checks IDS events, detects rogue APs, and determines the position of wireless stations.
  - **Sniffer**: You can configure an AP as a network sniffer using the controller. This mode captures and forwards all packets on a particular channel to a remote machine running packet analyzer software. These packets contain information on time stamps, signal strength, packet sizes, and so on. Sniffers allow you to monitor and record network activity and detect problems.
  - **Bridge**: The AP becomes a dedicated point-to-point or point-to-multipoint bridge. Two APs in bridge mode can connect two remote sites. Multiple APs can also form an indoor or outdoor mesh. Note that you cannot connect to the bridge with clients.
  - **Clear**: Returns the AP back to client-serving mode depending on the remote site tag configuration.
- **MAC Address**: Displays the registered MAC address on the controller.
- **Number of Slots** : Displays the number of slots supported by the AP.
- **Radio Type**: Displays the radio band configured on the controller. By default, both 802.11b/g/n (2.4-GHz) and 802.11a/n/ac (5-GHz) bands are enabled.
- **Slot ID**: Displays the slot on which radio is installed.
- **Sub band Type**: Displays the configured radio sub-band.
- **NDP Capability**: Displays the supported Neighbor Discovery Protocol (NDP) capability.
- **NDP Mode**: Displays the configured NDP mode. If the NDP mode that is configured is AUTO, the controller selects ON-Channel as the NDP mode. If the NDP-mode that is configured is OFF-Channel, the controller selects OFF-Channel as the NDP mode.

Verify NDP mode

Verify Neighbor Discovery Protocol Mode.

To verify the NDP mode, run these commands:

```
Device# show ap rf-profile name test-24g
Description                      : test
RF Profile Name                  : test-24g
Band                             : 2.4 GHz
Transmit Power Threshold v1      : -70 dBm
Min Transmit Power               : -10 dBm
Max Transmit Power               : 30 dBm
.
.
.
NDP mode                         : Auto
.
```

```
.
.
```

```
Device# show ap rf-profile name test-5g detail
Description                       : Test
RF Profile Name                   : test-5g
Band                              : 5 GHz
Transmit Power Threshold v1       : -70 dBm
Min Transmit Power                : -10 dBm
Max Transmit Power                : 30 dBm
.
.
.

63 6-GHz Band Operations

Topics:

- 6-GHz Band Support
- 6-GHz client steering

The 6-GHz band operations section introduces features and considerations unique to wireless communication on the 6-GHz radio band, enhancing connectivity and performance in modern Wi-Fi networks.

These topics describe the features that are specific to 6-GHz band radio.

6-GHz Band Support

The 6-GHz band operations section introduces features and considerations unique to wireless communication on the 6-GHz radio band, enhancing connectivity and performance in modern Wi-Fi networks.

Feature history

This table provides release and related information for the feature explained in this module.

Table 74: Feature history for 6 GHz band operations

Feature name	Release information	Feature description
6 GHz radio band support in Cisco Catalyst 9136I APs	Cisco IOS XE Cupertino 17.7.1	Cisco Catalyst 1936I Access Points support the 6 GHz radio band. This topic describes the 6 GHz band operations.
6 GHz client steering support in Cisco Catalyst 9136I APs	Cisco IOS XE Cupertino 17.7.1	6 GHz client steering occurs when the controller receives a periodic client statistics report from a 2.4 GHz band or the 5 GHz band. The client-steering configuration enabled under WLAN applies only to 6 GHz capable clients. Client steering is triggered if a client in the report is 6 GHz capable, redirecting the client to the 6 GHz band.

Configure preferred scanning channels in the RF profile (GUI)

Configure preferred scanning channels in the RF profile using GUI.

Complete this task to configure the preferred scanning channels in the RF profile in the WebUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. In the **RF** tab, click **Add**.
   The **Add RF Profile** page is displayed.
3. Click the **RRM** tab.
4. Click the **DCA** tab.
5. In the **Dynamic Channel Assignment** section, select the required channels in **DCA Channels** section.
6. In the **PSC Bias** field, click the toggle button to enable the preferred scanning channel bias for DCA.
7. Click **Apply to Device**.

The preferred scanning channels in the RF profile are configured.

Configure preferred scanning channels in RF profile (CLI)

Configure Preferred Scanning Channels in the RF Profile using commands.

Complete this task to configure preferred scanning channels in the RF profile.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile and enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 6ghz rf-profile rf-profile-name
   ```

3. Configure the RF Profile DCA settings and enable the bias for the preferred scanning channel for DCA.

   Example

   ```
   Device(config-rf-profile)# channel psc
   ```

The preferred scanning channels in the RF profile are configured.

Example

```
Device# configure terminal
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
Device(config-rf-profile)# channel psc
```

Configure broadcast probe response in RF profile (GUI)

Configure Broadcast Probe Response in RF Profile using GUI.

Complete this task to configure broadcast probe response in the RF profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. In the **RF** tab, click **Add**.
   The **Add RF Profile** page is displayed.
3. Click **802.11ax**.
4. In the **6 GHz Discovery Frames** section, click **Broadcast Probe Response**.
5. In the **Broadcast Probe Response Interval** field, enter the response time interval in milli-seconds (ms). The range is 5 ms to 25 ms. The default value is 20 ms.
6. Click **Apply to Device**.

The broadcast probe response in the RF profile is configured.

Configure broadcast probe response in RF profile (CLI)

Configure Broadcast Probe Response in RF Profile using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile and enter the RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 6ghz rf-profile rf-profile-name
   ```

3. Configure the broadcast probe response.

   Example

   ```
   Device(config-rf-profile)# dot11ax bcast-probe-response
   ```

4. Configure the broadcast probe response interval.

   Example

   ```
   Device(config-rf-profile)# dot11ax bcast-probe-response time-interval
   time-interval
   ```

The RF profile configuration includes the broadcast probe response.

Example

```
Device# configure terminal
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
Device(config-rf-profile)# dot11ax bcast-probe-response
Device(config-rf-profile)# dot11ax bcast-probe-response time-interval 20
```

Configure FILS discovery frames in RF profile (GUI)

Configure FILS Discovery Frames in the RF Profile using GUI.

Complete this task to configure FILS discovery frames in the RF profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. In the **RF** tab, click **Add**.
   The **Add RF Profile** page is displayed.
3. Click **802.11ax**.

4. In the **6 GHz Discovery Frames** section, click **FILS Discovery**.

> **Note**
>
> To prevent the transmission of discovery FILS frames when the discovery frames are set to **None** in the RF profile, ensure that you disable FILS discovery frames by either switching to the 5 GHz or the 2.4 GHz bands on the AP or by selecting the Broadcast Probe Response option.

5. Click **Apply to Device**.

The FILS discovery frames are configured in the RF profile.

Configure FILS discovery frames in RF profile (CLI)

Configure FILS Discovery Frames in the RF Profile using commands.

Complete this task to configure FILS discovery frames in the RF profile.

Procedure

---

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure an RF profile and enter the RF profile configuration mode.

Example

```
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
```

3. Configure the 802.11ax FILS discovery.

Example

```
Device(config-rf-profile)# dot11ax fils-discovery
```

> **Note**
>
> To prevent the transmission of discovery FILS frames when the discovery frames are set to **none** in the RF profile, disable FILS discovery frames by switching to the 5 GHz or 2.4 GHz bands on the AP, or by changing to Broadcast Probe Response.

The configuration of FILS discovery frames in the RF profile has been completed.

Example

```
Device# configure terminal
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
Device(config-rf-profile)# dot11ax fils-discovery
```

Configure multi BSSID profile (GUI)

Configure Multi BSSID Profile using GUI.

Complete this task by configuring the multi BSSID profile.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Multi BSSID**.
2. Click **Add**.
   The **Add Multi BSSID Profile** page is displayed.
3. Enter the name and the description of the BSSID profile.
4. Enter the following 802.11ax parameters:
   a) **Downlink OFDMA**
   b) **Uplink OFDMA**
   c) **Downlink MU-MIMO**
   d) **Uplink MU-MIMO**
   e) **Target Waketime**
   f) **TWT Broadcast Support**
5. Click **Apply to Device**.

The multi BSSID profile is configured.

Configure multi BSSID profile (CLI)

Configure Multi BSSID Profile using commands.

Complete this task to configure the multi BSSID profile for 6 GHz band radio.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the multi BSSID profile and enter the multi BSSID profile configuration.

   Example

   ```
   Device (config)# wireless profile multi-bssid multi-bssid-profile-name
   ```

3. Configure the 802.11ax parameters.

Example

```
Device (config-wireless-multi-bssid-profile)# dot11ax {downlink-mumimo |
downlink-ofdma | target-waketime  | twt-broadcast | uplink-mumimo |
uplink-ofdma}
```

The multi BSSID profile for 6 Ghz band radio is configured.

Example

```
Device# configure terminal
Device (config)# wireless profile multi-bssid multi-bssid-profile-name
Device (config-wireless-multi-bssid-profile)# dot11ax downlink-mumimo
```

Configure multi BSSID in RF profile (GUI)

Configure Multi-BSSID in the RF Profile using GUI.

Complete this task to configure multi BSSID in the RF profile.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **RF/Radio**.
2. In the **RF** tab, click **Add**.
   The **Add RF Profile** page is displayed.
3. Click the **802.11ax** tab.
4. In the **Multi BSSID Profile** field, choose the profile from the drop-down list.
5. Click **Apply to Device**.

Multi BSSID is configured in the RF profile.

Configure multi BSSID in RF profile (CLI)

Configure Multi BSSID in the RF Profile using commands.

Complete this task to configure multi BSSID in the RF profile.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an RF profile and enter RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 6ghz rf-profile rf-profile-name
   ```

3. Configure 802.11ax multi BSSID profile name in the RF profile configuration mode.

Example

```
Device(config-rf-profile)# dot11ax multi-bssid-profile multi-bssid-profile-name
```

The multi BSSID configuration in the RF profile is completed.

Example

```
Device# configure terminal
Device(config)# ap dot11 6ghz rf-profile rf-profile-name
Device(config-rf-profile)# dot11ax multi-bssid-profile multi-bssid-profile-name
```

Configure dynamic channel assignment freeze (CLI)

Configure Dynamic Channel Assignment Freeze using commands.

Complete this task to disable DCA for 6 GHz after the 6 GHz radios are stabilized with the right channels.

Before you begin
Ensure that Dynamic Channel Assignment (DCA) for 6 GHz is enabled. Wait for the 6 GHz radios to get stabilized with the right set of channel assignments.

Procedure

Disable DCA for 6 GHz bands.

Example

```
Device# no ap dot11 6ghz rrm channel dca global auto
```

DCA for 6 GHz radios is disabled.

6-GHz client steering

6-GHz Client Steering details.

6-GHz client steering is a network management feature that

- enables the steering of clients to the 6-GHz band based on periodic client statistics reports from the 2.4-GHz or 5-GHz bands
- is configured under WLAN settings, and
- applies only to clients that are 6-GHz capable.

The 6-GHz band offers additional channels, increased bandwidth, and reduced network congestion compared to the current 2.4-GHz and 5-GHz bands. Consequently, wireless clients with 6-GHz capability connect to the 6-GHz radio to leverage these advantages.

> **Note**
>
> Client steering to 6-GHz will not work if the SSID is used as OWE transition mode.

Configure 6-GHz client steering in global configuration mode (GUI)

Configure 6-GHz Client Steering in the Global Configuration Mode using GUI.

Complete this task to configure 6-GHz client steering in global configuration mode.

Procedure

1. Choose **Configuration** > **Wireless** > **Advanced**.
2. Click the **6 GHz Client Steering** tab. Client steering is configurable per WLAN.
3. In the **6 GHz Transition Minimum Client Count** field, enter a value to set the minimum number of clients for client steering. The default value is three clients. The range is from 0 to 200 clients.
4. In the **6 GHz Transition Minimum Window Size** field, enter a value to set the minimum window size of client steering. The default value is three. The range is from 0 to 200.
5. In the **6 GHz Transition Maximum Utilization Difference** field, enter a value to set the maximum utilization difference for steering. The range is from 0 to 100 percent. The default value is 20.
6. In the **6 GHz Transition Minimum 2.4 GHz RSSI Threshold** field, enter a value to set the minimum value for client steering 2.4-GHz RSSI threshold.
7. In the **6 GHz Transition Minimum 5 GHz RSSI Threshold** field, enter a value to set the minimum value for client steering 5-GHz RSSI threshold.
8. Click **Apply**.

The 6-GHz client steering is configured in the global configuration mode.

Configure 6-GHz client steering in global configuration mode (CLI)

Configure 6-GHz Client Steering in the Global Configuration Mode using commands.

Complete this task to configure 6-GHz client steering in the global configuration mode.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the minimum number of clients for client steering.

   Example

   ```
   Device(config)# client-steering client-count min-num-clients
   ```

The range is from 0 to 200.

3. Set the minimum window size of client steering.

Example

```
Device(config)# client-steering window-size window-size
```

The range is from 0 to 200.

4. Set the maximum channel utilization difference (2.4-GHz or 5-GHz to 6-GHz) for steering.

Example

```
Device(config)# wireless client client-steering util-threshold threshold
```

The range is from 0 to 100 percent.

5. Set the minimum value for the 2.4-GHz RSSI threshold for client steering.

Example

```
Device(config)# wireless client client-steering min-rssi-24ghz -70
```

6. Set the minimum value for the 5-GHz RSSI threshold for client steering.

Example

```
Device(config)# wireless client client-steering min-rssi-5ghz -75
```

The 6-GHz client steering is configured in the global configuration mode.

Example

```
Device# configure terminal
Device(config)# client-steering client-count 3
Device(config)# client-steering window-size 5
Device(config)# wireless client client-steering util-threshold 25
Device(config)# wireless client client-steering min-rssi-24ghz -70
Device(config)# wireless client client-steering min-rssi-5ghz -75
```

Configure 6-GHz client steering on WLAN (GUI)

Configure 6-GHz Client Steering on the WLAN using GUI.

Complete this task to configure 6 GHz client steering on WLAN.

Procedure

---

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. Click **Add**.
   The **Add WLAN** page is displayed.
3. Click **Advanced**.
4. Check the **6 GHz Client Steering** check box to enable client steering on the WLAN.

5. Click **Apply to Device**.

The 6 GHz client steering on WLAN is configured.

Configure 6-GHz client steering on WLAN (CLI)

Configure 6-GHz Client Steering on the WLAN using commands.

Complete this task to configure 6 GHz client steering on WLAN.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the WLAN configuration submode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid-name
   ```

3. Configure 6-GHz client steering on the WLAN.

   Example

   ```
   Device(config-wlan)# client-steering
   ```

The 6-GHz client steering on WLAN is configured.

Example

```
Device# configure terminal
Device(config)# wlan wlan-name 18 ssid-name
Device(config-wlan)# client-steering
```

Verify 6-GHz client steering

Verify 6-GHz Client Steering.

To verify client steering, run the following commands:

```
Device# show wlan wlan-id
                WLAN Profile Name     : wlan1
                ================================================
                Identifier                                    : 1
                Description                                   :
                Network Name (SSID)                           : ssid-demo
                Status                                        : Disabled
                Broadcast SSID                                : Enabled
```

```
                .
                .
                .
                6Ghz Client Steering                              : Enabled
                .
                .
                .
```

```
Device# show wireless client steering
                Client Steering Configuration Information
                Macro to micro transition threshold                 : -55 dBm

                Micro to Macro transition threshold                 : -65 dBm

                Micro-Macro transition minimum client count          : 3
                Micro-Macro transition client balancing window      : 3
                Probe suppression mode                             : Disabled

                Probe suppression transition aggressiveness         : 3
                Probe suppression hysteresis                        : -6 dB
                6Ghz transition minimum client count                : 3
                6Ghz transition minimum window size                 : 3
                6Ghz transition maximum channel util difference     : 20%
                6Ghz transition minimum 2.4Ghz RSSI threshold       : -60 dBm

                6Ghz transition minimum 5Ghz RSSI threshold         : -65 dBm

                WLAN Configuration Information

                WLAN Profile Name                     11k Neighbor Report
   11v BSS Transition

64 AP Packet Capture

Topics:

- AP client packet capture

AP client packet capture

Introduces the AP client packet capture feature, outlining its use for wireless client troubleshooting by capturing and filtering packets on APs, uploading captures to an FTP server, and supporting network engineers in analyzing over-the-air traffic to diagnose connectivity or performance issues.

An AP client packet capture is a diagnostic feature that

- enables packet capture on APs for the purpose of wireless client troubleshooting
- filters and captures packets on the channel and radio where the AP is operating, and
- uploads the captured packets to a file on an FTP server for later analysis (for example, in Wireshark).

Feature history

Table 75: Feature history for AP client packet capture

Feature name	Release information	Feature description
AP client packet capture	Cisco IOS XE 16.7.1	The AP client packet capture feature enables packet capture on APs, filters and captures packets on the channels and radios, and uploads the captured packets to a file.

This feature allows network engineers to analyze over-the-air traffic as observed by the AP, helping identify connectivity or performance issues experienced by wireless clients. For instance, when debugging why a client device cannot connect to a Wi-Fi network, engineers can use AP client packet capture to record and examine all packets exchanged between the client and the AP.

Limitations of AP client packet capture

The limitations of AP client packet capture include:

- You can perform packet capture for only one client at a time per site.
- You can start packet capture on a specific AP or a set of APs using static mode.

  When you start packet capture in auto mode, the system selects nearby APs to capture packets for a specific client. In auto mode, you cannot start or stop packet capture on an individual AP. Use the **stop all** command to stop packet capture when it is started in auto mode.
- After the Single Sign-On (SSO) process is complete, the packet capture stops after a switchover.

Enable packet capture (GUI)

Enable Packet Capture using GUI.

Enable packet capture on selected network interfaces.

Procedure

1. Choose **Troubleshooting** > **Packet Capture**.
2. Click **Add**. Enter the name that identifies the capture point.

3. From the **Filter** drop-down list, choose if you want to capture IPv4 or IPv6 packets. For IPv4, provide the source and destination addresses and the subnet mask. For IPv6, enter the source and destination addresses and the prefix length.
4. Check the **Monitor Control Plane** check box to configure the control plane as an attachment point.
5. Check the **DHCP** check box to enable **Inner Filter Protocol**.
6. Enter the **Inner Filter MAC address** using one of the standard MAC address formats: xx:xx:xx:xx:xx:xx, xx-xx-xx-xx-xx-xx, or xxxx.xxxx.xxxx.
7. Type the capture buffer size. The default buffer is 10 MB.
8. Specify the session limit either in seconds or in the number of packets captured.
9. Select the interfaces from which you want to capture packets, in the **Available** list. Click the arrow button to move it to the **Selected** list.
10. Click **Apply to Device**.

Packet capture is active on the chosen interfaces, and captured packet data is available for analysis.

Enable packet capture (CLI)

Enable Packet Capture using commands.

Enable packet capture for a specified client.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

2. Enable packet capture for the specified client on a set of nearby APs.

   Example

   ```
   Device# ap packet-capture start client-mac-address auto
   ```

Packet capture is now enabled on your specified client.

```
Device# enable
Device# ap packet-capture start 0011.0011.0011 auto
```

Create AP packet capture profile and map to an AP join profile (GUI)

Create AP Packet Capture Profile and Map to an AP Join Profile using GUI.

Add a packet capture profile to an AP join profile so you can monitor APs.

Procedure

1. Click **Configuration** > **Tags & Profiles** > **AP Join Profile**.

2. Click **Add** to create a new AP Join Profile and enter the required details.
3. In the **Add AP Join Profile** area, click **AP** > **Packet Capture**.
4. Click the **Plus** icon to create a new Packet Capture profile or select a profile from the dropdown menu.
5. Click **Save**.

The AP join profile now includes a packet capture profile. This change enables packet capture for associated APs.

Create AP packet capture profile and map to an AP join profile

Create AP Packet Capture Profile and Map to an AP Join Profile using commands.

Create and enable an AP packet capture profile, then associate it with a specific AP join profile to facilitate packet capture for targeted APs.

Packet capture profile configurations apply to individual APs. The packet capture profile is assigned to an access point profile, which is then mapped to a site tag.

When starting packet capture, APs apply the packet capture profile configurations associated with their site and AP join profile.

Procedure

---

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile.

   Example

   ```
   Device(config)# wireless profile ap packet-capture packet-capture-profile-name
   ```

3. Configure an AP packet capture profile.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

4. Enable packet capture in the AP profile.

   Example

   ```
   Device(config-ap-profile)# packet-capture profile-name
   ```

5. Exit the AP profile configuration mode.

   Example

   ```
   Device(config-ap-profile)# end
   ```

6. Check the detailed information for the selected AP packet capture profile.

Example

```
Device# show wireless profile ap packet-capture detailed profile-name
```

The AP packet capture profile is successfully created and mapped to the selected AP join profile.

```
Device# configure terminal
Device(config)# wireless profile ap packet-capture test1
Device(config)# ap profile ap-profile1
Device(config-ap-profile)# packet-capture capture-profile
Device(config-ap-profile)# end
Device# show wireless profile ap packet-capture detailed test1
```

Start or stop packet capture

Start or Stop Packet Capture using commands.

You can start or stop wireless packet capture for a specific client using CLI commands.

Procedure

1. Enable packet capture for a specific client.

   Example

   ```
   Device# ap packet-capture stop client-mac-address {auto | static | ap-name}
   ```

2. Disable packet capture for a specific client.

   Example

   ```
   Device# ap packet-capture stop client-mac-address {all | static | ap-name}
   ```

The system starts or stops packet capture for the selected client on the specified AP.

```
Device# ap packet-capture start 0011.0011.0011 auto
Device# ap packet-capture stop 0011.0011.0011 all
```

65 DHCP Option82

Topics:

- DHCP Option 82
- Configure DHCP Option 82 global interface
- Configure DHCP Option 82 through a VLAN interface
- AP DHCP Option 82 support on FlexConnect local switching mode

DHCP Option 82

Outlines the functions and security benefits of DHCP Option 82, describes its suboptions and relay agent information, and details controller configuration options for including network-specific identifiers and enabling address allocation based on topology or client characteristics.

DHCP Option 82 is a relay agent information option that

- carries information known by the relay agent
- increases DHCP security by enabling identification of request sources, and
- allows address allocation based on network topology or client device characteristics.

The controller can be configured to add Option 82 information to DHCP requests from clients before forwarding the requests to a DHCP server. The DHCP server can then be configured to allocate IP addresses to the wireless client based on the information present in DHCP Option 82.

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. Configuration parameters and other control information are carried in tagged data items stored in the Options field of the DHCP message. These data items are also called options. Option 82 includes information known by the relay agent.

The Relay Agent Information option is a single DHCP option containing one or more suboptions that convey information known by the Relay Agent. Option 82 enables a DHCP Relay Agent to insert circuit-specific information into a forwarded request to a DHCP server. This option uses two suboptions:

- Circuit ID: The Circuit ID suboption includes information that is specific to the circuit the request came in on. This suboption is an identifier that is specific to the relay agent. Thus, the circuit that is described will vary depending on the relay agent.
- Remote ID: The Remote ID suboption includes information on the remote host-end of the circuit. This suboption usually contains information that identifies the relay agent. In a wireless network, this is likely a unique identifier for the wireless AP.

Note

- All valid Remote ID combinations are separated by a colon (:) as the delimiter.
- IP MAC binding is required for DHCP Option 82 to work in some situations.

DHCP Option 82 configuration options

You can configure these DHCP Option 82 options in a controller:

- DHCP Enable
- DHCP Opt82 Enable
- DHCP Opt82 Ascii
- DHCP Opt82 RID
- DHCP Opt Format
- DHCP AP MAC
- DHCP SSID

- DHCP AP ETH MAC
- DHCP AP NAME
- DHCP Site Tag
- DHCP AP Location
- DHCP VLAN ID

The controller includes the SSID in ASCII format and the VLAN ID in hexadecimal format within the remote ID suboption of Option 82 in the outgoing DHCP packets to the server for this configuration.

```
ipv4 dhcp opt82 format ssid
ipv4 dhcp opt82 format vlan-id
```

However, if *ipv4 dhcp opt82 ascii* configuration is also present, the controller adds VLAN-ID and SSID in ASCII format.

For Cisco Catalyst 9800 Series Configuration Best Practices, see the following link: https://www.cisco.com/c/en/us/products/collateral/wireless/catalyst-9800-series-wireless-controllers/guide-c07-743627.html

Configure DHCP Option 82 format

Configure DHCP Option 82 Format using commands.

Configure the wireless controller to insert DHCP Option 82 information into DHCP requests from wireless clients.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable configuration for the specified profile policy.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

3. Shut down the profile policy.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Assign the profile policy to a VLAN.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-name
   ```

5. Optional: Set the session timeout value in seconds. The range is between 20 to 86,400 seconds.

Example

```
Device(config-wireless-policy)# session-timeout value-btwn-20-86400
```

6. Optional: Set the idle timeout value in seconds. The range is between 15 to 100,000 seconds.

   Example

   ```
   Device(config-wireless-policy)# idle-timeout 15
   ```

7. Enable central switching.

   Example

   ```
   Device(config-wireless-policy)# central switching
   ```

8. Enable DHCP Option 82 for the wireless clients.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp opt82
   ```

9. Optional: Enable ASCII on the DHCP Option 82 feature.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp opt82 ascii
   ```

10. Optional: Add Cisco 2-byte Remote ID (RID) to the DHCP Option 82 feature.

    Example

    ```
    Device(config-wireless-policy)# ipv4 dhcp opt82 rid
    ```

11. Enable DHCP Option 82 on the corresponding AP.

    Example

    ```
    Device(config-wireless-policy)# ipv4 dhcp opt82 format {ap_ethmac | ap_location
     | apmac | apname | policy_tag | ssid | vlan_id}
    ```

    For information on the various options available with the command, see Cisco Catalyst 9800 Series Wireless Controller Command Reference .

12. Enable the profile policy.

    Example

    ```
    Device(config-wireless-policy)# no shutdown
    ```

The wireless profile policy inserts DHCP Option 82 information in the specified format for wireless clients.

```
Device# configure terminal
Device(config)# wireless profile policy pp3
Device(config-wireless-policy)# shutdown
Device(config-wireless-policy)# vlan 72
Device(config-wireless-policy)# session-timeout 300
Device(config-wireless-policy)# idle-timeout 15
Device(config-wireless-policy)# central switching
Device(config-wireless-policy)# ipv4 dhcp opt82
Device(config-wireless-policy)# ipv4 dhcp opt82 ascii
Device(config-wireless-policy)# ipv4 dhcp opt82 rid
Device(config-wireless-policy)# ipv4 dhcp opt82 format apmac
Device(config-wireless-policy)# no shutdown
```

Configure DHCP Option 82 global interface

Outlines global DHCP Option 82 configuration using server override settings and different SVIs, including relay agent information setup, link selection suboption enablement, and use of specified source interfaces for DHCP message relaying.

Configure DHCP Option 82 globally through server override (CLI)

Configure DHCP Option 82 Globally Through Server Override using commands.

Set up DHCP Option 82 settings to override relay agent information in DHCP packets at the server.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Insert the global server override and link selection suboptions.

   Example

   ```
   Device(config)# ip dhcp-relay information option server-override
   ```

The system processes DHCP Option 82 information globally based on server settings.

```
Device# configure terminal
Device(config)# ip dhcp-relay information option server-override
```

Configure DHCP Option 82 through server override (CLI)

Configure DHCP Option 82 Through Server Override using commands.

To enable precise DHCP Option 82 behavior, configure the server override and link-selection suboptions.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the server override suboption to either an RFC-specific value or a proprietary value.

   Example

   ```
   Device(config)# ip dhcp compatibility suboption server-override [cisco |
   standard]
   ```

3. Set the link selection suboption to either an RFC-specific value or a proprietary value.

   Example

   ```
   Device(config)# ip dhcp compatibility suboption link-selection [cisco |
   standard]
   ```

DHCP Option 82 operates according to the configured settings.

```
Device# configure terminal
Device(config)# ip dhcp compatibility suboption server-override cisco
Device(config)# ip dhcp compatibility suboption link-selection cisco
```

Configure DHCP Option 82 globally through different SVIs (GUI)

Configure DHCP Option 82 Globally Through Different SVIs using GUI.

Enable DHCP Option 82 to insert relay information for clients across selected SVIs.

Procedure

1. Choose **Configuration > VLAN**.
2. Select a VLAN from the drop-down list.

   The **Edit SVI** window appears.

3. Click the **Advanced** tab.
4. Select an option from the **IPv4 Inbound ACL** drop-down list.
5. Select an option from the **IPv4 Outbound ACL** drop-down list.
6. Select an option from the **IPv6 Inbound ACL** drop-down list.
7. Select an option from the **IPv6 Outbound ACL** drop-down list.
8. Enter an IP address in the **IPv4 Helper Address** field.
9. Set the status to **Enabled** if you want to enable the **Relay Information Option** setting.
10. Enter the **Subscriber ID**.
11. Set the status to **Enabled** if you want to enable the **Server ID Override** setting.
12. Set the status to **Enabled** if you want to enable the **Option Insert** setting.

13. Select an option from the **Source-Interface Vlan** drop-down list.
14. Click **Update & Apply to Device**.

DHCP Option 82 is enabled for the selected SVIs. This allows relay agent information to be included in DHCP requests.

Configure DHCP Option 82 globally through different SVIs (CLI)

Configure DHCP Option 82 Globally Through Different SVIs using commands.

Enable DHCP Option 82 globally so that DHCP relayed messages include option 82 information through the specified SVIs.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set global source interface for relayed messages.

   Example

   ```
   Device(config)# ip dhcp-relay source-interface vlan vlan-id
   ```

The device globally applies DHCP relay with Option 82 information using the specified SVI interface.

```
Device# configure terminal
Device(config)# ip dhcp-relay source-interface vlan 72
```

Configure DHCP Option 82 through a VLAN interface

Outlines procedures for configuring DHCP Option 82 on VLAN interfaces and SVIs using commands such as option-insert, server-ID-override, and subscriber-ID, including steps for VLAN and SVI setup, suboption configuration, IP assignment, UDP relay settings, and disabling MOP features for DHCP relay control.

Configure DHCP Option 82 through option-insert command (CLI)

Configure DHCP Option 82 Through Option-Insert Command using commands.

Enable DHCP Option 82 insertion on a VLAN interface to provide relay agent information in DHCP packets.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a VLAN ID.

Example

```
Device(config)# interface vlan vlan-id
```

3. Insert relay information in BOOTREQUEST.

Example

```
Device(config-if)# ip dhcp relay information option-insert
```

4. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address
```

5. Configure the destination address for UDP broadcasts.

Example

```
Device(config-if)# ip helper-address ip-address
```

6. Disable the MOP for an interface.

Example

```
Device(config-if)# no mop enabled
```

7. Disable the task of sending MOP periodic system ID messages.

Example

```
Device(config-apgroup)# no mop sysid
```

DHCP requests sent from this VLAN interface will contain Option 82 relay information to aid in DHCP server assignment and troubleshooting.

```
Device# configure terminal
Device(config)# interface vlan 72
Device(config-if)# ip dhcp relay information option-insert
Device(config-if)# ip address 9.3.72.38 255.255.255.0
Device(config-if)# ip helper-address 9.3.72.1
Device(config-if)# no mop enabled
Device(config-apgroup)# no mop sysid
```

Configure DHCP Option 82 through server-ID-override command (CLI)

Configure DHCP Option 82 through the server-ID-override command.

Enable DHCP Option 82 with server-ID override to control how DHCP relay information is inserted on a Cisco device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the server-id override suboption to use an RFC-specific or Cisco-specific value.

   Example

   ```
   Device(config)# ip dhcp compatibility suboption server-override cisco
   ```

3. Configure the link-selection suboption to use an RFC-specific or Cisco-specific value.

   Example

   ```
   Device(config)# ip dhcp compatibility suboption link-selection cisco
   ```

4. Configure a VLAN ID.

   Example

   ```
   Device(config)# interface vlan vlan-id
   ```

5. Insert the server-id override suboption and link-selection suboption.

   Example

   ```
   Device(config-if)# ip dhcp relay information option server-id-override
   ```

6. Configure the IP address for the interface.

   Example

   ```
   Device(config-if)# ip address ip-address
   ```

7. Configure the destination address for UDP broadcasts that your interfce will use.

   Example

   ```
   Device(config-if)# ip helper-address ip-address
   ```

8. Disable MOP for an interface.

Example

```
Device(config-if)# no mop enabled
```

9. Disable the task of sending MOP periodic system ID messages.

Example

```
Device(config-if)# [no] mop sysid
```

The device uses the specified server-id override and link-selection options in DHCP Option 82 relay messages, which the device forwards through the configured VLAN interface.

```
Device# configure terminal
Device(config)# ip dhcp compatibility suboption server-override cisco
Device(config)# ip dhcp compatibility suboption link-selection cisco
Device(config)# interface vlan 72
Device(config-if)# ip dhcp relay information option server-id-override
Device(config-if)# ip address 9.3.72.38 255.255.255.0
Device(config-if)# ip helper-address 9.3.72.1
Device(config-if)# no mop enabled
Device(config-if)# no mop sysid
```

Configure DHCP Option 82 through a subscriber-ID (CLI)

Configure DHCP Option 82 through a Subscriber-ID using commands.

Configure DHCP Option 82 through a subscriber-ID.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a VLAN ID.

Example

```
Device(config)# interface vlan vlan-id
```

3. Insert the subscriber identifier suboption to include the subscriber ID in DHCP messages.

Example

```
Device(config-if)# ip dhcp relay information option subscriber-id subscriber-id
```

4. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address
```

5. Configure the destination address for UDP broadcasts.

Example

```
Device(config-if)# ip helper-address ip-address
```

6. Disable MOP for an interface.

Example

```
Device(config-if)# no mop enabled
```

7. Disable the task of sending MOP periodic system ID messages.

Example

```
Device(config-apgroup)# no mop sysid
```

The system now inserts the subscriber-ID suboption (DHCP Option 82) into relayed DHCP packets on the specified VLAN interface.

```
Device# configure terminal
Device(config)# interface vlan 72
Device(config-if)# ip dhcp relay information option subscriber-id test10
Device(config-if)# ip address 9.3.72.38 255.255.255.0
Device(config-if)# ip helper-address 92.0.2.1
Device(config-if)# no mop enabled
Device(config-apgroup)# no mop sysid
```

Configure DHCP Option 82 through server-ID-override and subscriber-ID commands (CLI)

Configure DHCP Option 82 Through server-ID-override and subscriber-ID using commands.

Enable customized handling of DHCP Option 82 information for relayed DHCP requests by setting server and subscriber ID options.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a VLAN ID.

Example

```
Device(config)# interface vlan vlan-id
```

3. Insert server ID override and link selection suboptions.

Example

```
Device(config-if)# ip dhcp relay information option server-id-override
```

4. Insert the subscriber identifier suboption.

Example

```
Device(config-if)# ip dhcp relay information option subscriber-id subscriber-id
```

5. Configure the IP address for the interface.

Example

```
Device(config-if)# ip address ip-address
```

6. Configure the destination address for UDP broadcasts.

Example

```
Device(config-if)# ip helper-address ip-address
```

7. Disable the MOP for an interface.

Example

```
Device(config-if)# no mop enabled
```

8. Disable the task of sending MOP periodic system ID messages.

Example

```
Device(config-apgroup)# no mop sysid
```

The interface relays DHCP requests with Option 82 data, including server ID override and subscriber ID.

```
Device# configure terminal
Device(config)# interface vlan 72
Device(config-if)# ip dhcp relay information option server-id-override
Device(config-if)# ip dhcp relay information option subscriber-id test10
Device(config-if)# ip address 9.3.72.38 255.255.255.0
Device(config-if)# ip helper-address 9.3.72.1
Device(config-if)# no mop enabled
Device(config-apgroup)# no mop sysid
```

Configure DHCP Option 82 through different SVIs (CLI)

Configure DHCP Option 82 Through Different SVIs using commands.

Enable DHCP Option 82 using different switch virtual interfaces (SVIs) for relayed requests.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a VLAN ID.

   Example

   ```
   Device(config)# interface vlan vlan-id
   ```

3. Configure a source interface on the VLAN to relay messages.

   Example

   ```
   Device(config-if)# ip dhcp relay source-interface vlan vlan-id
   ```

4. Configure the IP address for the interface.

   Example

   ```
   Device(config-if)# ip address ip-address
   ```

5. Configure the destination address for UDP broadcasts.

   Example

   ```
   Device(config-if)# ip helper-address ip-address
   ```

6. Disable the Maintenance Operations Protocol (MOP) on the interface.

   Example

   ```
   Device(config-if)# no mop enabled
   ```

7. Disable periodic system ID message transmission for MOP.

   Example

   ```
   Device(config-apgroup)# no mop sysid
   ```

The device relays DHCP messages with Option 82 through the configured VLAN SVIs.

```
Device# configure terminal
Device(config)# interface vlan 72
Device(config-if)# ip dhcp relay source-interface vlan 74
Device(config-if)# ip address 9.3.72.38 255.255.255.0
Device(config-if)# ip helper-address 9.3.72.1
Device(config-if)# no mop enabled
Device(config-apgroup)# no mop sysid
```

AP DHCP Option 82 support on FlexConnect local switching mode

Describes AP DHCP Option 82 Support on FlexConnect Local Switching Mode.

AP DHCP Option 82 support on FlexConnect local switching mode is a DHCP relay feature that

- provides additional information on the physical attachment of the client
- enhances security while using DHCP for network address allocation, and
- enables the AP to act as a DHCP relay agent to prevent DHCP client requests from unreliable sources.

DHCP Option 82 functionality

As a DHCP relay agent, the AP can add DHCP Option 82 information such as AP MAC, AP Name, and SSID to DHCP requests from clients before forwarding the requests to the DHCP server. Afterward, the DHCP servers can allocate IP addresses to wireless clients based on the data contained within DHCP Option 82.

> **Note**
>
> This feature is supported only in FlexConnect Local Switching mode.

Configure AP DHCP Option82 support

Configure AP DHCP Option82 support using commands.

Enable DHCP Option82 support on access points to provide additional network information to DHCP servers.

DHCP Option82 allows access points to insert additional information such as AP MAC address, AP name, or SSID into DHCP requests from clients. This information helps DHCP servers make more informed decisions about IP address assignments and network policies.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable configuration for the specified profile policy.

Example

```
Device(config)# wireless profile policy policy-name
```

Example

```
Device(config)# wireless profile policy policy-ap
```

3. Shut down the profile policy.

Example

```
Device(config-wireless-policy)# shutdown
```

4. Configure the AP MAC address or the AP name format to be added to DHCP requests from clients before forwarding them to the DHCP server.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 format apmac|apname
```

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 format apmac
```

You can use either apmac or apname, but not both.

5. Configure the unique SSID format to be added to DHCP requests from clients before forwarding them to the DHCP server.

Example

```
Device(config-wireless-policy)# ipv4 dhcp opt82 format ssid
```

6. Enable the profile policy.

Example

```
Device(config-wireless-policy)# no shutdown
```

DHCP Option82 support is now configured on the access point policy, allowing the AP to insert additional network information into DHCP requests from connected clients.

Verify AP DHCP Option82 support

Provides commands to verify AP DHCP Option82 support configuration and status.

Verify the configured parameters for DHCP Option82 using commands on the AP console and controller to confirm the configuration status and settings.

To verify the configured parameters for DHCP Option82, use this command on the AP console:

Note

You can fetch information about the WLAN and WLAN ID using the **show flexconnect WLAN** command.

```
Device# show flexconnect dhcp option-82 wlan 1

DHCP OPTION 82 CONFIG FOR WLAN:
VAP ID      :0
Format      :Binary
Delimiter   :":"
Circuit-ID  :
Remote-ID   :
    AP Name
    SSID-Name
```

To verify whether DHCP Option82 is enabled on the controller, use this command:

```
Device# show wireless profile policy detailed

Opt82
  SSID                      : ENABLED
  AP_ETHMAC                 : DISABLED
  APNAME                    : ENABLED
```

66 RADIUS Authentication and Accounting

Topics:

- RADIUS realms
- RADIUS accounting of AP events
- RADIUS call station identifier
- RADIUS VSA

RADIUS realms

RADIUS Realm details.

A RADIUS realm is an AAA configuration element that

- enables assigning authentication and accounting requests to specific RADIUS servers based on user domain information
- uses the domain portion of a user's Network Access Identifier (NAI) to select the appropriate RADIUS server, and
- provides realm-based filtering and control for authentication and accounting requests within a WLAN.

Feature history
Table 76: Feature history for RADIUS realms

Feature name	Release information	Feature description
RADIUS realms	Cisco IOS XE 16.9.1	RADIUS realms are configuration elements in AAA (Authentication, Authorization, and Accounting) systems. They use the domain portion of a user's Network Access Identifier (NAI)–such as the part after "@" in an email address–to direct authentication and accounting requests to specific RADIUS servers. Realms help organizations manage user access and resource usage across different groups or domains.

When mobile clients connect to a WLAN, the RADIUS realm is included in the Extensible Authentication Protocol Method for UMTS Authentication and Key Agreement (EAP-AKA) identity response of the authentication request packet. For WLAN, the NAI format for EAP-AKA can be specified as *username@domain.com*. In the NAI format, the realm follows the @ symbol and is specified as *example.com*. If the vendor-specific attribute "test" is added, the NAI format becomes *test@example.com*.

The RADIUS Realm feature can be enabled and disabled on a WLAN. If Realm is enabled on a WLAN, the corresponding user should send the username in the NAI format. The controller sends the authentication request to the AAA server only after it receives a realm in NAI format from the client and verifies that the realm complies with the required standards. Additionally, the controller sends accounting requests to the AAA server based on realm filtering.

Realm support on a WLAN

Each WLAN is configured to support NAI realms. Once the realm is enabled on a specific SSID, the system compares the received realms in the EAP identity response to those configured on the RADIUS server. If a username with the realm is not sent by the client, the WLAN uses the default RADIUS server for authentication. When the client's realm does not match the realms configured on the WLAN, the client is deauthenticated and dropped.

If the RADIUS Realm feature is not enabled on a WLAN, the controller uses the username received in the EAP identity request directly and authenticates the user using the configured RADIUS server. The RADIUS Realm feature is disabled on WLANs by default.

- **Realm match for authentication**: In dot1x with EAP methods (similar to EAP AKA), the username is received as part of an EAP identity response. A realm is derived from the username and is matched with the realms that are already configured in the corresponding RADIUS authentication server. If there is a match, the authentication requests are forwarded to the RADIUS server. If there is a mismatch, the client is deauthenticated.

- **Realm match for accounting**: After receiving a client's username through an access-accept message, the system derives the realm from the username when accounting messages are triggered. The realm is compared with the configured accounting realms on the RADIUS accounting server. When there is a match, the server receives the accounting requests. If there is no match, the system drops the accounting requests.

Enable RADIUS realm

Enable RADIUS Realm using commands.

Enable the RADIUS realm to allow the WLAN to use the RADIUS realm selection for AAA authentication.

Enabling the RADIUS realm is required when configuring wireless AAA policies that use RADIUS for authentication on your Cisco device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new AAA policy.**wireless aaa policy**

   Example

   ```
   Device(config)# wireless aaa policy aaa-policy
   ```

3. Enable AAA RADIUS realm selection.

   Example

   ```
   Device(config-aaa-policy)# aaa-realm enable
   ```

   Note

   Use the **no aaa-realm enable** or the **default aaa-realm enable** command to disable the RADIUS realm.

The AAA RADIUS realm is now enabled and available for authentication purposes in the specified wireless AAA policy.

```
Device# configure terminal
Device(config)# wireless aaa policy policy-1
Device(config-aaa-policy)# aaa-realm enable
```

Configure realm to match the RADIUS server for authentication and accounting

Configure Realm to Match the RADIUS Server for Authentication and Accounting using commands.

Configure the realm to use your chosen RADIUS server group for authentication and accounting network access requests.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a AAA authentication model.

   Example

   ```
   Device(config)# aaa new-model
   ```

3. Set the authorization method.

   Example

   ```
   Device(config)# aaa authorization network default group radius-server-group
   ```

4. Indicate that 802.1x must use the realm group RADIUS server.

   Example

   ```
   Device(config)# aaa authentication dot1x realm group radius-server-group
   ```

5. Define the authentication method at login.

   Example

   ```
   Device(config)# aaa authentication login realm group radius-server-group
   ```

6. Enable accounting so the system sends a start record notice when a client is authorized and a stop record notice when the session ends.

   Example

   ```
   Device(config)# aaa accounting identity realm start-stop group
   radius-server-group
   ```

Your device now uses the realm and RADIUS server group for authentication, authorization, and accounting.

```
Device# configure terminal
Device(config)# aaa new-model
Device(config)# aaa authorization network default group aaa_group_name
Device(config)# aaa authentication dot1x cisco.com group cisco1
Device(config)# aaa authentication login cisco.com group cisco1
Device(config)# aaa accounting identity cisco.com start-stop group v
```

Configure AAA policy for WLANs

Configure the AAA Policy for a WLAN using commands.

Configure authentication, authorization, and accounting (AAA) policies to control and secure access for WLAN users.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new AAA policy for wireless.

   Example

   ```
   Device(config)# wireless aaa policy aaa-policy-name
   ```

3. Enable AAA RADIUS server selection by realm.

   Example

   ```
   Device(config-aaa-policy)# aaa-realm enable
   ```

4. Return to global configuration mode.

   Example

   ```
   Device(config-aaa-policy)# exit
   ```

5. Configure a WLAN policy profile.

   Example

   ```
   Device(config)# wireless profile policy wlan-policy-profile
   ```

6. Map the AAA policy.**aaa-policy***aaa-policy*

   Example

   ```
   Device(config-wireless-policy)# aaa-policy aaa-policy
   ```

7. Set the accounting list.**accounting-list***acct-config-realm*

   Example

   ```
   Device(config-wireless-policy)# accounting-list acct-config-realm
   ```

8. Return to global configuration mode.

   Example

   ```
   Device(config-wireless-policy)# exit
   ```

9. Configure a WLAN.**wlan***wlan-namewlan-idssid*

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid
   ```

10. Enable the security authentication list for IEEE 802.1x.

    Example

    ```
    Device(config-wlan)# security dot1x authentication-list auth-list-realm
    ```

11. Return to global configuration mode.

    Example

    ```
    Device(config-wlan)# exit
    ```

12. Configuresa policy tag.

    Example

    ```
    Device(config)# wireless tag policy policy-name
    ```

13. Map a policy profile to the WLAN.

    Example

    ```
    Device(config-policy-tag)# wlan wlan-name policy policy-profile
    ```

14. Return to global configuration mode.

    Example

    ```
    Device(config-policy-tag)# exit
    ```

The AAA policy is successfully applied to the target WLAN, enabling centralized authentication and accounting for users connecting to that WLAN.

```
Device# configure terminal
Device(config)# wireless aaa policy aaa-policy-1
Device(config-aaa-policy)# aaa-realm enable
Device(config-aaa-policy)# exit
Device(config)# wireless profile policy wlan-policy-1
Device(config-wireless-policy)# aaa-policy aaa-policy-1
Device(config-wireless-policy)# accounting-list cisco.com
Device(config-wireless-policy)# exit
Device(config)# wlan wlan2 14 wlan-aaa
Device(config-wlan)# security dot1x authentication-list cisco.com
Device(config-wlan)# exit
Device(config)# wireless tag policy tag-policy-1
Device(config-policy-tag)# wlan Abc-wlan policy wlan-policy-a
Device(config-policy-tag)# exit
```

Verify RADIUS-realm configuration

Verify the RADIUS-Realm Configuration.

Run this command to verify the RADIUS-realm configuration.

```
Device# show wireless client mac-address 14bd.61f3.6a24 detail

RADIUS accounting of AP events

Introduces accounting of AP events, providing instructions for configuring accounting method lists within AP profiles, verifying AP accounting information, and implementing AAA accounting using named and predefined method lists through CLI-based procedures.

RADIUS accounting of AP events is a network monitoring mechanism that

- Tracks the status transitions of APs within a wireless controller environment
- Records AP join and disjoin events
- Provides historical visibility into AP downtime and uptime through accounting messages sent to a RADIUS server.

Feature History

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 77: Feature history table

Feature Name	Release	Description
Device Ecosystem Data	Cisco IOS XE 17.10.1	This feature sends device analytics data that is present in the RADIUS accounting request to Cisco ISE to profile endpoints The command is introduced: • dot11-tlv-accounting
Chargeable User Identity in RADIUS Accounting	Cisco IOS XE 17.9.1	Chargeable User Identity (CUI) is a unique identifier for a client visiting a network. This attribute can be used as an alternative for the client's username as part of the authentication process. The command is introduced: • dot11-tlv-accounting
Improved Logging in RADIUS Accounting	Cisco IOS XE 17.1.1	Prior to Cisco IOS XE Amsterdam 17.1.1 release, the controller did not send accounting messages for AP join and disjoin events during network issues. From Cisco IOS XE Amsterdam 17.1.1 Release and later, the RADIUS server keeps a record of all APs that were down and have come up.

Configure accounting method-list for an AP profile

Configure Accounting Method-List for an AP Profile using commands.

Define an accounting method list within an access point (AP) profile to enable or disable accounting for AP operations.

Use this task to specify how accounting is managed for an AP profile on your device. This allows tracking of AP events and assists with auditing and troubleshooting

Before you begin

- Identify the AP profile name you want to configure. The default AP profile name is `default-ap-profile`.
- Determine the accounting method list name you wish to apply.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the AP profile. The default AP join profile name is default-ap-profile.

Example

```
Device(config)# ap profile ap-profile-name
```

3. Configure the accounting method list for the AP profile.

Example

```
Device(config-ap-profile)# [no] accounting method-list method-list-name
```

Use the **no** form of this command to disable the accounting method list.

The system associates the specified accounting method list with the AP profile, enabling or disabling accounting

Example

```
Device# configure terminal
Device(config)# ap profile ap-profile-name
Device(config-ap-profile)# [no] accounting method-list method-list-name
```

Verify AP accounting information

Verify the AP Accounting Information.

Verify the AP accounting information, including the MAC address, packets sent, packets received, and the method list.

```
Device#show wireless stats ap accounting
Base MAC       Total packet Send    Total packet Received Methodlist
-------------------------------------------------------------------------------
00b0.e192.0f20     4       3    abc
38ed.18cc.5788     8       8         ML_M
70ea.1ae0.af08     0       0         ML_A
```

View details for a method list configured for an AP profile.

```
Device# show ap profile name Method-list detailed
AP Profile Name               : test-profile
Description                   :
.
.
.
Method-list name              : Method-list
Packet Sequence Jump DELBA    : ENABLED
Lag status                    : DISABLED
.
Client RSSI Statistics
  Reporting                   : ENABLED
  Reporting Interval          : 30 seconds
```

Configure AAA accounting using default method list (CLI)

Use this task to enable and configure AAA command accounting to monitor and record user command activity using the default method list on your device.

Use this task to monitor and record user command activity on devices through AAA accounting features.

Configure AAA accounting to track user commands executed on a controller, leveraging the default accounting method. This supports compliance and security needs.

Before you begin

- Confirm that AAA is enabled on the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an accounting method list and enables accounting.

   Example

   ```
   Device(config)# aaa accounting commands 15 default start-stop group group-name
   ```

   - *privilege_level*: AAA accounting level. The valid range is from zero to 15.
   - *group-name*: AAA accounting group that supports only TACACS+ group.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The controller records user command activities according to the configured accounting method.

Configure HTTP command accounting using named method list (CLI)

Use this task to configure HTTP command accounting on your device, allowing you to monitor and record user command activity with AAA features using a named method list.

Set up command accounting to track user actions on network devices via HTTP with a specified AAA method list using commands.

HTTP command accounting provides auditing and compliance by recording commands executed by users. Using a named method list offers flexibility for different accounting requirements.

Before you begin

- Ensure AAA accounting is enabled on your device.
- Have a predefined AAA accounting method list (if not, configure one).

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure HTTP command accounting using the named method list.

   Example

   ```
   Device(config)# ip http accounting commands 1 oneacct
   ```

   - *level*: The privilege value ranges from zero to 15. By default, the command privilege levels available on the controller are:
     - *0*: Includes the **disable**, **enable**, **exit**, **help**, and **logout** commands.
     - *1*: Includes all the user-level commands at the controller prompt (>).
     - *15*: Includes all the enable-level commands at the controller prompt (>).
   - *named-accounting-method-list*: Name of the predefined command accounting method list.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device records user command activities in accordance with the configured accounting method.

RADIUS call station identifier

Explains how RADIUS call station identifiers are used in network access scenarios to specify the network endpoint a client attempts to access and how this information supports authorization policies.

A RADIUS call station identifier is an attribute in the RADIUS protocol that

- allows a Network Access Server (NAS) to specify information about the endpoint (the called station) that a client is trying to access
- is included in Access-Request packets (as Called-Station-Id), and
- enables network policies by providing context for authorization decisions.

Use cases

- In dial-up scenarios, the attribute can contain the phone number dialed by the user. The NAS captures this attribute in the Access-Request packet using Dialed Number Identification (DNIS) or similar technology.
- For IEEE 802.1X authenticators (wired or wireless network access), the attribute can contain the MAC address of the bridge or AP, formatted as ASCII text.

Role in RADIUS authorization

- The RADIUS server can use this attribute to define which MAC addresses, network segments, or called stations a client is allowed to access.
- The RADIUS server can restrict or allow access based on the network resource or location to which the client is connecting. However, this is possible only in configurations that support preauthentication. In these configurations, a client attempts to authenticate before fully connecting.

The **Called-Station-Id** attribute enables the NAS to specify to the RADIUS server which endpoint or resource the client is requesting. The server uses this information to enforce connection policies.

> **Note**
>
> The **Called-Station-Id** attribute applies only to Access-Request packets, not to Access-Accept or CoA-Request packets.

Feature history for RADIUS call station identifier

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 78: Feature history for RADIUS call station identifier

Release	Feature Information
Cisco IOS XE Bengaluru 17.4.1	The RADIUS called station identifier configuration is enhanced to include more attributes. The newly added options for authentication and accounting are: • policy-tag-name • flex-profile-name • ap-macaddress-ssid-flexprofilename • ap-macaddress-ssid-policytagname • ap-macaddress-ssid-sitetagname • ap-ethmac-ssid-flexprofilename • ap-ethmac-ssid-policytagname • ap-ethmac-ssid-sitetagname For more information on the attributes listed above, see the commands: • **radius-server attribute wireless accounting call-station-id** • **radius-server attribute wireless authentication call-station-id**

Configure a RADIUS call station identifier

Use this task to specify a custom call station (Called-Station-ID) identifier in RADIUS authentication and accounting messages for policy tracking and assignment.

Set a custom call station identifier (**Called-Station-ID**) for RADIUS authentication and accounting messages sent from the device.

Use this task to specify a policy tag name or identifier in RADIUS messages for better tracking or policy assignment.

Before you begin

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a call station identifier sent in the RADIUS authentication messages.

   Example

   ```
   Device(config)# radius-server attribute wireless authentication call-station-id
    policy-tag-name
   ```

3. Configure a call station identifier sent in the RADIUS accounting messages.

   Example

   ```
   Device(config)# radius-server attribute wireless accounting call-station-id
   policy-tag-name
   ```

The specified policy tag name is now included as the **Called-Station-ID** in all RADIUS authentication and accounting messages.

RADIUS VSA

RADIUS VSA details.

A RADIUS VSA is a vendor-specific attribute used in RADIUS implementations that

- allows vendors to communicate specialized information between a network access server and a RADIUS server
- enables support for attributes not defined by standard RADIUS specifications, and
- is included in authentication or accounting packets, or both, according to implementation needs.

The main elements of the VSA are:

- Type: Identifies the attribute type.
- Length: Indicates attribute length.

- String (Data): Contains vendor-specific data, which includes:
  - Vendor ID
  - Vendor type
  - Vendor length
  - Vendor data

Supported modes and attributes

Authentication and accounting requests per WLAN support these VSAs in addition to the existing AAA attributes.

Table 79: Newly supported attributes

Attribute name	Well-known attribute	VSA sub-attribute	Vendor ID
SVR-Zip-Code	26	14	14369
SVR-Device-Type	26	17	14369
SVR-Device-Model-Number	26	18	14369
SVR-Lat-Long	26	19	14369
SVR-Venue-Category	26	20	14369
SVR-Network-Type	26	21	14369
Aggregation-AAA	26	22	14369
BW-Venue-Id	26	7	22472
BW-Venue-TZ	26	8	22472
BW-Class	26	10	22472
BW-Venue-Description	26	11	22472
BW-ISO-Country-Code	26	14	22472
BW-E164-Country-Code	26	15	22472
BW-State-Name	26	16	22472
BW-City-Name	26	17	22472
BW-Area-Code	26	18	22472
BW-User-Group	26	27	22472
BW-Venue-Name	26	29	22472
BW-Operator-Name	26	37	22472

> **Note**
>
> You can use this feature only in FlexConnect central authentication mode with local switching. FlexConnect local authentication mode is not supported. Use this feature for wireless sessions only.

Create an attribute list

Create an Attribute List using commands.

Create a custom AAA attribute list for use in policy mapping.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a AAA attribute list.

   Example

   ```
   Device(config)# aaa attribute list attribute-list
   ```

3. Specify a AAA attribute type.

   Example

   ```
   Device(config-attr-list)# attribute type attribute-type
   Device(config-attr-list)# attribute type BW-City-Name "MUMBAI"
   ```

4. Optional: Specify a AAA attribute type such as the state name.

   Example

   ```
   Device(config-attr-list)# attribute type BW-State-Name "MAHARASHTRA"
   ```

5. Optional: Specify a AAA attribute type such as the venue name.

   Example

   ```
   Device(config-attr-list)#attribute type BW-Venue-Name "WANKHEDE"
   ```

6. Return to Privileged EXEC mode.

Example

```
Device(config-attr-list)# end
```

After you create the AAA attribute list, you can use it in policy mapping.

What to do next

Create a AAA policy and map the attribute list.

Map a AAA policy to WLAN policy profile

Map a AAA Policy to the WLAN Policy Profile using commands.

Associate a AAA policy with a WLAN policy profile. This enforces authentication and authorization rules on wireless clients.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy EAP-AKA profile-policy
   ```

3. Create a new AAA policy.

   Example

   ```
   Device(config-wireless-policy)# aaa-policy Verizon-aaa-policy aaa-policy
   ```

4. Return to Privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

You have mapped the AAA policy to the WLAN policy profile.

What to do next

Map the WLAN policy profile to a WLAN.

Map the WLAN policy profile to a WLAN

Map the WLAN Policy Profile to a WLAN using commands.

Associate a previously configured WLAN policy profile to a WLAN on a Cisco device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a new policy tag.

   Example

   ```
   Device(config)# wireless tag policy policy-name
   ```

3. Map the policy profile to a WLAN.

   Example

   ```
   Device(config-policy-tag)# wlan wlan-profile-name policy aaa-policy
   ```

4. Return to Privileged EXEC mode.

   Example

   ```
   Device(config-policy-tag)# end
   ```

The specified WLAN policy profile is successfully mapped to the WLAN.

```
Device# configure terminal
Device(config)# wireless tag policy EAP-AKA
Device(config-policy-tag)# wlan EAP-AKA policy EAP-AKA
Device(config-policy-tag)# end
```

67 Cisco StadiumVision

Topics:

- Cisco StadiumVision

Introduces Cisco StadiumVision, outlining its key features and guiding users through wireless controller parameter configuration via GUI and CLI, along with reference procedures for verification and successful deployment.

Cisco StadiumVision

Outlines Cisco StadiumVision functionality, providing procedures to configure wireless controller parameters using both GUI and CLI methods, and includes reference steps for verifying configurations.

Cisco StadiumVision is a high-definition IPTV solution that:

- provides advanced digital content management and delivery,
- transforms the appearance and atmosphere of venues, and
- is built on the Cisco Connected Stadium solution.

This technology enables replay of critical moments of a game on Wi-Fi-capable devices.

To enable Cisco StadiumVision on the controller , you need to configure these parameters:

1. On the Wireless Controller :
   - Multicast Data Rate
   - RX Sensitivity SOP
   - Multicast Buffer
2. CAPWAP
3. AP Radio Driver and Firmware:
   - Multicast Data Rate
   - RX Sensitivity SOP
   - Multicast Buffer

Configure Cisco StadiumVision parameters (GUI)

Configure Cisco StadiumVision using GUI.

This task describes how to configure parameters for Cisco StadiumVision using the GUI.

Procedure

1. Choose **Configuration > Wireless > Advanced**.
2. Click the **High Density** tab.
3. Set the **Multicast Data Rate** for 5 GHz radio or 2.4 GHz radio using the respective drop-down lists.
4. Click **Apply** to save the settings.

Upon completion, the wireless parameters for StadiumVision will be configured successfully.

Configure Cisco StadiumVision parameters (CLI)

Configure parameters for Cisco StadiumVision using commands.

This task provides instructions for configuring various parameters in Cisco StadiumVision, including WLAN, enhanced multicast buffer size, and radio receive sensitivity SOP thresholds.

- Multicast buffer and data rate configurations are supported for all AP models.

Procedure

1. Configure WLAN

   Example

   ```
   Device(config)# wlan wlan1 10
   ```

   Configures a WLAN.

2. Configure enhanced multicast buffer size

   Example

   ```
   Device(config-wlan)# multicast buffer 45
   ```

   Configures enhanced multicast buffer size between 30 (default) and 60 on a WLAN.

   > **Note**
   >
   > You can enable only two out of the possible 512 WLANs configured on the controller and embedded wireless controller for enhanced multicast buffers.

3. Configure the radio receive sensitivity SOP threshold

   Example

   ```
   Device(config)# ap dot11 [5ghz| 24ghz] rx-sop threshold custom -70
   ```

   Configures the radio receive sensitivity SOP threshold between -60 to -85 dB, which can also be configured as predefined auto, low, high, medium values specific to 5ghz or 24ghz bands.

   By default, the configuration is disabled and its value is set to *auto*. If the RxSOP value of *auto* (0) is pushed, then the AP considers the value burnt-in during manufacturing.

Upon completion of these configurations, the Cisco StadiumVision system will operate with the new settings applied, enhancing performance and compatibility based on the configured parameters.

Verify StadiumVision configurations

Verify StadiumVision configurations.

- **show ap rf-profile name** *rf-name* **detail**
- **show ap dot11 5ghz** *high-density*

Rx SOP

```
Device#show ap rf-profile name Typical_Client_Density_rf_5gh detail | i SOP
Rx SOP Threshold                : auto
```

Multicast Buffer

```
Device#show wlan id 1 | sec Buffer
Multicast Buffer                              : Enabled
Multicast Buffer Size                         : 45

Device#

Device#sh wlan name vwlc-OpenAuth | inc Buffer

68 Persistent SSID Broadcast

Topics:

- Persistent SSID broadcast

This chapter explains the persistent SSID broadcast feature for Cisco Aironet 1542 RAPs and MAPs, providing command steps to enable or disable it and commands to verify AP configuration and behavior when the WAN link is down.

Persistent SSID broadcast

Explains how persistent SSID broadcasts allow mesh access points to continue broadcasting the SSID even if WAN connectivity is lost, supporting network troubleshooting and management in Cisco Aironet 1542 APs operating in Flex+Bridge mode.

A persistent SSID broadcast is a wireless network feature that

- enables Root APs (RAPs) and Mesh APs (MAPs) to continue broadcasting the SSID when the WAN link is down
- helps operators isolate issues between the backhaul network and the access wireless network, and
- applies specifically to Cisco Aironet 1542 APs operating in FlexConnect plus Bridge mode.

RAPs have a wired connection to the controller while MAPs have wireless connection to the controller .

This requirement helps isolate responsibility, whether the fault lies with the backhaul or the access wireless network. Different operators may own each part of the network.

RAPs and MAPs broadcast the SSID while in standalone mode if the default gateway is reachable.

Also refer Mesh Deployment Guide for Cisco Catalyst 9800 Series Wireless Controllers.

Configure persistent SSID broadcast (CLI)

Use this procedure to configure or disable persistent SSID broadcast on an access point profile using commands.

Enable or disable persistent SSID broadcast so that associated APs re-join and maintain SSID visibility as configured using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Configure the SSID broadcast mode.

   Example

   ```
   Device(config-ap-profile)# ssid broadcast persistent
   ```

   ```
   Device(config-ap-profile)# [no] ssid broadcast persistent
   ```

   The **persistent** keyword enables a persistent SSID broadcast, where the associated APs re-join. Use the **no** form of the command to disable the feature.

> **Note**
>
> Enabling or disabling this feature causes the AP to re-join.

Verify persistent SSID broadcast

This section lists the command and relevant output fields used to confirm the persistent SSID broadcast status on Cisco APs.

To view the configuration of all Cisco APs, use this **show** command:

```
Device#show ap config general
Cisco AP Name   : AP4C77.6DF2.D598
=================================================
Office Extend Mode                                : Disabled
Persistent SSID Broadcast                         : Enabled
Remote AP Debug                                   : Disabled
```

69 Network Monitoring

Topics:

- Network monitoring

Network monitoring

Introduces network monitoring systems, highlighting real-time data collection through APIs, use of NETCONF/YANG for automation and programmability, and mechanisms for synchronous status updates and asynchronous notifications, including integration with third-party applications and key operational considerations in Cisco environments.

A network monitoring system is a network management solution that

- collects and exposes real-time operational data from network devices through APIs
- uses protocols such as NETCONF/YANG, and other technologies to automate data transfer and enable programmability, and
- provides synchronous status updates and asynchronous notifications for alarms, events, and third-party applications.

Network monitoring systems can expose APIs or push data to third-party applications. In Cisco environments, data transfer commonly occurs through the NETCONF/YANG protocol, supporting automated and programmable network operations.

- The two types of information provided are:
  - Status information received synchronously: NETCONF is the management interface for status information received synchronously. It allows publishing the operational state of the device, including the controller.
  - Alarm and event information sent asynchronously: NETCONF/YANG push is used for alarm and event information. It provides the mechanism for sending subscribed NETCONF notifications.
- Contact API or Developer Support for NETCONF/YANG features at this link:

  https://developer.cisco.com/site/support/#

> **Note**
>
> When using NETCONF, you may see a user named \"yang_mgmt_infra"\ appearing in accounting records for TACACS or RADIUS. This user is internal. If you pull data from Cisco IOS, you should expect to see this user.

Status information received synchronously - configuration examples

Configuration example for Status Information, Alarm and Event Information.

You can use the NETCONF/YANG interface to fulfill customer requests.

To enable Status Information, Alarm Information, and Event Information, configure the NETCONF server on the controller using this command.

netconf-yang

> **Note**
>
> The Cisco Catalyst 9800 wireless controller supports only RSA keys for the trustpoint used by the ncsshd process. EC keys are not supported; using them causes the ncsshd process to crash and prevents you from using NETCONF.

The **netconf-yang** command enables notifications, configuration access, and operation access (OAM) through NETCONF/YANG. For details about the NETCONF/YANG, refer to the *NETCONF Protocol* chapter of the Programmability Configuration Guide at https://www.cisco.com/c/en/us/support/ios-nx-os-software/ios-xe-17/products-installation-and-configuration-guides-list.html

For the Status Information Received Synchronously type, NETCONF exports these items:

- Name of the village
- APs in each village
- Status of each AP
- Number of clients currently connected and logged on in each village and each AP

All the data for the items listed above is already available as the controller operational data exported through NETCONF. The examples below explain where the data items listed are available.

This command is used in the controller:

```
wireless tag site village_name_1
```

The site tags can be retrieved by NETCONF using the **get-config** operation.

Example output for **Name of the Village**:

```
<site-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-site-cfg">
[...]
<site-tag-configs>
  <site-tag-config>
    <site-tag-name>village_name_1</site-tag-name>
    <description>custom user site tag for a village</description>
  </site-tag-config>
[...]
</site-tag-configs>
```

The operational data for the controller lists all connected (joined) APs and their corresponding site tags. Each output entry includes detailed information about the access point and its site tag. The relevant fields and controller show commands are presented here:

Example output of **AP per Village**:

```
<data>
    <access-point-oper-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-access-point-oper">
    [...]
      <radio-oper-data>
        <wtp-mac>00:1b:0c:00:02:00</wtp-mac>   #show ap dot11 {24ghz|5ghz}
summary "MAC Address"
        <radio-slot-id>0</radio-slot-id>       #show ap dot11 {24ghz|5ghz}
summary "Slot"
        <ap-mac>00:1b:0c:00:02:00</ap-mac>
        <slot-id>0</slot-id>
        <radio-type>1</radio-type>             # 1 - 2.4GHz, 2 - 5GHz
```

```
        <admin-state>enabled</admin-state>     #show ap dot11 {24ghz|5ghz}
summary "Admin State"
        <oper-state>radio-up</oper-state>      #show ap dot11 {24ghz|5ghz}
summary "Oper State"
    [...]
[...]
      <capwap-data>
        <wtp-mac>00:1b:0c:00:02:00</wtp-mac>                #show ap summary
 "Radio MAC"
        <ap-operation-state>registered</ap-operation-state> #show ap summary
 "State"
        <ip-addr>10.102.140.10</ip-addr>                    #show ap summary
 "IP Address"
        [...]
        <admin-state>1</admin-state>              #show ap status   "Status",
 1 - Enabled, 2 - Disabled
       <location>default-location </location>    #show ap summary  "Location"

        <country-code>CH </country-code>
        <name>AP_A-1</name>                        #show ap summary  "AP Name"

 [...]
        <tag-info>
          [...]
          <site-tag>
           <site-tag-name>village_name_1</site-tag-name> #show ap name AP_A-1
 config general "Site Tag Name"
            [...]
          </site-tag>
[...]
```

The operational data of the controller contains information about all connected wireless clients. This includes detailed device-related information, such as MAC address, IP address, state, and access point name.

Example output of the **Number of clients currently online and logged in each village and each AP**:

```
<data>
    <client-oper-data
xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-client-oper">
      <common-oper-data>
        <client-mac>00:00:1a:04:00:02</client-mac>     #show wireless client
summary  "MAC Address"
        <ap-name>AP_A-1</ap-name>                      #show wireless client

Alarm and Event Information Received Asynchronously - Configuration Examples

Configuration examples for Alarm and Event Information Received Asynchronously.

The push functionality for the alarm and event information is fulfilled with on-change notifications through NETCONF dynamic subscriptions, with XML encoding.

Example output of **AP Up/Down Events - Subscription**

```

70 Creating a Lobby Ambassador Account

Topics:

- Lobby ambassador account

Lobby ambassador account

Explains the function and capabilities of lobby ambassador accounts for managing guest user access in Cisco network environments.

A lobby ambassador account is a user account that

- allows designated personnel (lobby ambassadors) to create and delete guest users on the network
- allows lobby ambassadors to assign guest user parameters such as password, life span, and role profile, and
- restricts lobby ambassadors from creating WLAN or web authentication policies.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 80: Feature history for lobby ambassador account

Feature Name	Release Information	Feature Description
Lobby ambassador account	Cisco IOS XE Dublin 17.2.x	From Cisco IOS XE Cupertino 17.2.x onwards, lobby administrators can add or delete a client from the allowed list to manage the association with a WLAN or SSID.

As a global administrator, you create a lobby ambassador user to manage guest accounts.

Configure the RADIUS server with the Cisco-AV-pair privilege level set greater than zero to enable lobby ambassador functionality.

Note

An administrator can create lobby ambassador accounts remotely using a RADIUS or TACACS server, or locally.

Only the administrator can create WLAN policies, web authentication policies, and AAA attribute lists. Lobby ambassadors use these attribute lists to map guest users to role profiles, including Quality-of-Service profiles.

After upgrading to Cisco Catalyst 9800 Controller software release 17.2.x, clear the browser cache to correctly view the lobby admin GUI.

Create a lobby ambassador user account

Create a lobby ambassador user account using the GUI and CLI.

You can configure administrator or lobby ambassador usernames and passwords to prevent unauthorized users from reconfiguring the controller and viewing configuration information.

Create a user account (GUI)

Create a user account using the GUI.

Add a new user account to the system.

Procedure

1. Choose **Administration** > **User Administration**.
2. Click **Add**.
3. In the **User Name** field, enter a user name for the new account.
4. Select the policy that you want to associate with the user from the **Policy** drop-down list.
5. Select the privilege level that you want to associate with the user by clicking the user privilege icon from the **Privilege** drop-down list. The options are:
   - **Go to Basic Mode**
   - **Go to Advanced Mode**

   Go to Basic Mode: This privilege level defines the commands that users enter using the CLI after they have logged into the device. Privilege one allows access in user EXEC mode and privilege 15 allows access in Privileged EXEC mode.

   Go to Advanced Mode:

   Admin: Users with Privilege 15 can execute all the **show**, **config**, and **exec** commands on the device. These users will have access to all GUI sections.

   Read Only: Users with Privileges one to 14 are considered read-only users. The default privilege is one if a user is created using the GUI. These users have access only to the Dashboard and the Monitoring sections.

   No Access: Users with Privilege zero can log in to the device through Telnet or SSH to access the CLI, but cannot access the GUI.

   Lobby Admin: Users who can create only guest user accounts. Lobby ambassadors can create and delete guest users and set parameters such as:
   - Password.
   - Lifetime of the guest user.
   - Guest role profiles (Quality-of-Service) profiles that should be applied on a guest using the AAA attribute list.
6. In the **Password** field, enter a password for the new account.
7. In the **Confirm Password** field, enter the same password again to confirm again.
8. Click **Apply to Device**.

Log in using the lobby account

Use commands to log in using the lobby account.

Execute the following commands before logging in using the lobby credentials:

- **aaa new-model**
- **aaa authorization exec default local**
- **ip http authentication aaa**

Log out from the administrator account. Then, log in using the lobby credentials. After logging in, the **Guest User** page appears.

Create a lobby ambassador account (CLI)

Create a lobby ambassador account using commands.

Add a new lobby ambassador (guest network administrator) to the system using CLI commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a user account.

   Example

   ```
   Device(config)# user-name user-name example-user
   ```

3. Specify the account type as lobby admin.

   Example

   ```
   Device(config-user-name)# type lobby-admin
   ```

4. Create a password for the lobby administrator account.

   Example

   ```
   Device(config-user-name)# password 0 password example-password
   ```

5. Create an attribute list for lobby admin access.

   Example

   ```
   Device(config-user-name)# aaa attribute list user-name example-user
   ```

6. Create an attribute type for lobby admin access.

   Example

   ```
   Device(config-user-name)# attribute type wlan-profile-name wlan_wl_mab
   ```

7. Return to the global configuration mode.

   Example

   ```
   Device(config-user-name)# exit
   ```

71 Lobby Ambassador Account

Topics:

- Lobby ambassador account

Lobby ambassador account

Explains the function and capabilities of lobby ambassador accounts for managing guest user access in Cisco network environments.

A lobby ambassador account is a user account that

- allows designated personnel (lobby ambassadors) to create and delete guest users on the network
- allows lobby ambassadors to assign guest user parameters such as password, life span, and role profile, and
- restricts lobby ambassadors from creating WLAN or web authentication policies.

Feature history

Create a lobby ambassador user account

Create a lobby ambassador user account using the GUI and CLI.

You can configure administrator or lobby ambassador usernames and passwords to prevent unauthorized users from reconfiguring the controller and viewing configuration information.

Create a user account (GUI)

Create a user account using the GUI.

Add a new user account to the system.

Procedure

1. Choose **Administration** > **User Administration**.
2. Click **Add**.
3. In the **User Name** field, enter a user name for the new account.
4. Select the policy that you want to associate with the user from the **Policy** drop-down list.
5. Select the privilege level that you want to associate with the user by clicking the user privilege icon from the **Privilege** drop-down list. The options are:
   - **Go to Basic Mode**
   - **Go to Advanced Mode**

   Go to Basic Mode: This privilege level defines the commands that users enter using the CLI after they have logged into the device. Privilege one allows access in user EXEC mode and privilege 15 allows access in Privileged EXEC mode.

   Go to Advanced Mode:

   Admin: Users with Privilege 15 can execute all the **show**, **config**, and **exec** commands on the device. These users will have access to all GUI sections.

   Read Only: Users with Privileges one to 14 are considered read-only users. The default privilege is one if a user is created using the GUI. These users have access only to the Dashboard and the Monitoring sections.

   No Access: Users with Privilege zero can log in to the device through Telnet or SSH to access the CLI, but cannot access the GUI.

   Lobby Admin: Users who can create only guest user accounts. Lobby ambassadors can create and delete guest users and set parameters such as:
   - Password.
   - Lifetime of the guest user.
   - Guest role profiles (Quality-of-Service) profiles that should be applied on a guest using the AAA attribute list.
6. In the **Password** field, enter a password for the new account.
7. In the **Confirm Password** field, enter the same password again to confirm again.
8. Click **Apply to Device**.

Log in using the lobby account (CLI)

Execute the following commands before logging in using the lobby credentials:

Procedure

1. Enable NEW access control commands and functions.

   Example

   ```
   aaa new-model
   ```
2. Enter the local database.

Example

```
aaa authorization exec default local
```

3. Set HTTP server authentication method and use AAA access control methods.

Example

```
ip http authentication aaa
```

Log out from the administrator account. Then, log in using the lobby credentials. After logging in, the **Guest User** page appears.

Create a lobby ambassador account (CLI)

Create a lobby ambassador account using commands.

Add a new lobby ambassador (guest network administrator) to the system using CLI commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Create a user account.

Example

```
Device(config)# user-name user-name example-user
```

3. Specify the account type as lobby admin.

Example

```
Device(config-user-name)# type lobby-admin
```

4. Create a password for the lobby administrator account.

Example

```
Device(config-user-name)# password 0 password example-password
```

5. Create an attribute list for lobby admin access.

Example

```
Device(config-user-name)# aaa attribute list user-name example-user
```

6. Create an attribute type for lobby admin access.

   Example

   ```
   Device(config-user-name)# attribute type wlan-profile-name wlan_wl_mab
   ```

7. Return to the global configuration mode.

   Example

   ```
   Device(config-user-name)# exit
   ```

Configure WLAN (GUI)

Configure a WLAN using the GUI.

Set up a new WLAN on your wireless controller using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **WLANs**.
2. In the **WLANs** window, click the name of the **WLAN** or click **Add** to create a new one. The **Add/Edit WLAN** window is displayed.
3. In the **Add/Edit WLAN** window, click the **General** tab to configure these parameters.
   - In the **Profile Name** field, enter or edit the name of the profile.
   - In the **SSID** field, enter or edit the SSID name.

     The SSID name is alphanumeric and can be up to 32 characters in length.
   - In the **WLAN ID** field, enter or edit the ID number. The valid range is between one and 512.
   - Select the **802.11** radio band from the **Radio Policy** drop-down list.
   - Using the **Broadcast SSID** toggle button, change the status to either **Enabled** or **Disabled**.
   - Using the **Status** toggle button, change the status to either **Enabled** or **Disabled**.
4. Click the **Security** tab, and then select the **Layer 2** tab to configure these parameters:
   - Select **None** from the **Layer 2 Security Mode** drop-down list. This setting disables Layer 2 security.
   - Enter the **Reassociation Timeout** value, in seconds. This value specifies the duration before a fast transition reassociation times out.
   - Check the **Over the DS** check box to enable Fast Transition over a distributed system.
   - Choose **OWE**. Opportunistic Wireless Encryption (OWE) provides data confidentiality with encryption over the air between an AP radio and a wireless client. OWE Transition Mode ensures backwards compatibility.
   - Choose Fast Transition (802.11r), the IEEE standard for fast roaming. This standard allows the initial handshake with a new AP to occur before the client roams to the target AP. This method is known as Fast Transition.
   - Check the check box to enable MAC filtering in the WLAN.
   - Check the **Lobby Admin Access** check box to enable Lobby Admin access.

5. Click **Save & Apply to Device**.

Client allowed list

Client allowed list details.

A client allowed list is a WLAN security feature that

- enables creation of an allowed list for clients on a particular WLAN or SSID-based MAC address, and
- is supported only with MAC addresses that do not include delimiters.

If you create a new client MAC address as an allowed list user with an invalid WLAN profile name, map the client MAC address to the WLAN profile carefully.

If you are a client in a university or hotel, you may need network access for a limited time. Many guests bring multiple devices. Protect networks from misuse or unauthorized access and allow legitimate clients to connect.

There are two types of administrator roles:

- Global Administrator: Creates a lobby admin user on the controller and enables each lobby administrator to access the WLAN.
- Lobby Administrator: Adds or deletes clients from the allowed list using the GUI to manage association to a WLAN or SSID. Existing lobby administrators can also configure the allowed list.

Restrictions for client allowed list

Client allowed list restrictions.

A lobby admin can add clients to the allowed list only through the GUI, not through the CLI.

Creating a client allowed list (GUI)

Create a client allowed list using GUI.

As a lobby administrator, you can use several methods to create an allowed list for valid WLAN users.

Adding single MAC address to allowed list

Add single MAC address to allowed list using the GUI.

Import a specific MAC address into your WLAN whitelist efficiently using the admin portal.

Procedure

1. Log in to the Lobby Admin portal.
2. Click **Whitelist Users**.
3. Select **WLAN** from the drop-down list.
4. Click **Add New Whitelist User**.
5. Click **By MAC Address** radio button.
6. Enter the **MAC address** and **Description**.
7. Click **Apply to Device**.

Adding bulk MAC address to allowed list

Add bulk MAC address to allowed list using the GUI.

Import multiple MAC addresses into your WLAN whitelist efficiently using the admin portal.

Procedure

1. Log in to the Lobby Admin portal.
2. Click **Whitelist Users**.
3. Select the WLAN from the drop-down list.
4. Click **Add New Whitelist User**.
5. Click **Bulk Import** radio button.
6. Select the CSV file that lists the clients in MAC address, description format.
7. Click **Apply to Device**.

Manage guest users (GUI)

Manage guest users using the GUI.

Add and manage guest user access through the controller GUI.

Procedure

1. Log in to the Lobby Admin portal using the lobby admin credentials.
2. Click **Whitelist Users**.
3. Select the corresponding **WLAN** from the **WLAN** drop-down list.
4. Select **Onboarding** from the **WLAN Mode** to enable clients to access the network.
5. Click **Apply**.
6. Select a MAC address from the **Connected/Not Whitelisted** in the Whitelist window. Once the clients join the controller, the MAC addresses are listed in the **Connected/Not Whitelisted**. In the Onboarding mode, MAC filtering in the selected WLAN is disabled. In such a scenario, change the mode using **Secure** mode.
7. Select **Secure** to automatically add the clients that are connected to the allowed list. In the secure mode, MAC filtering in the selected WLAN is enabled.
8. Click **Apply to Device**.

   The clients are listed in the **Connected/Whitelisted**.

View a client allowed list

View a client allowed list using the GUI.

See which clients are connected or whitelisted on a WLAN.

Procedure

1. Log in to the Lobby Admin portal.
2. Click **Whitelist Users**.

3. Select the corresponding **WLAN** from the **WLAN** drop-down list.

   The window lists the following information:

   - **Connected/Whitelisted**: Lists the clients that are connected and added to the allowed list by the Lobby admin.
   - **Connected/Not Whitelisted**: Lists the clients that are connected, but not added to the allowed list by the Lobby admin.
   - **Not Connected/Whitelisted**: Lists the clients that are not connected, but added to the allowed list.

72 Guest User Accounts

Topics:

- Create guest user accounts

This chapter explains how administrators and lobby ambassadors create, configure, verify, and assign temporary guest user accounts for WLAN access using GUI and commands, including lifetime, simultaneous-login limits, and WLAN-specific username binding.

Create guest user accounts

Explains guest user accounts, which provide temporary, restricted access to wireless networks for visitors through accounts configured by administrators or designated lobby ambassadors.

A guest user account is a user account type that

- grants temporary access to a WLAN or SSID
- is created by a network administrator or lobby ambassador, and
- automatically expires after a configured duration.

The controller can provide guest user access on WLANs. You must create guest user accounts to enable this access. The lobby ambassador has limited configuration privileges and can access only the web pages used to manage guest user accounts.

The lobby ambassador can specify how long guest user accounts remain active.

You can associate a user name with a WLAN profile name to restrict guest users to a specific WLAN.

Prerequisites for guest users

- Guest users are created by administrator or lobby ambassador.
- Guest user should be role-based.
- Guest users should be able to connect to the network and access the internet.
- Guest users configured locally or remotely (through RADIUS or TACACS) do not have access to the device through Telnet, SSH, or WebUI.

Create a guest user account (GUI)

Learn how to create a guest user account using the web interface, including specifying credentials, configuring session parameters, and saving the account for device access.

Enable guest access by adding a new user account in the system through the GUI.

Procedure

1. Choose **Configuration** > **Security** > **Guest User**.
2. On the **Guest User** page, click **Add**.
3. Enter a user name, password, and description for the new account. Check the **Generate password** check box to automatically generate a password.
4. Enter the number of simultaneous user logins. The valid values range between 0 to 64.

   Enter zero for unlimited users.
5. In the **Lifetime** section, choose the number of years, months, days, hours, and minutes.
6. Click **Save & Apply to Device**.

Create a guest user account (CLI)

Learn how to create a guest user account on the device using commands.

Enable temporary or guest access to your network by creating a guest user account with specific attributes and access limitations using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a guest user account.

   Example

   ```
   Device(config)# user-name guest-user-name
   ```

3. Specify the account type as guest user account.

   Example

   ```
   Device(config-user-name)# type network-user description description guest-user
    max-login-limit number of simultaneous logins lifetime year yy month mm day
    day hour hour minute minute second second
   ```

   > **Note**
   >
   > User configuration values must be equal to or lower than the global values, since global values take precedence.
   >
   > The command **max-user-login** configured at the global level, overrides the session limit configured at the local user level. The value range is from 0 to 8.

4. Create a password for the guest user account.

   Example

   ```
   Device(config-user-name)# password 0 password
   ```

   If FIPS mode is enabled, configure the guest user's password with an encryption level greater than six by entering the command **algorithm-type sha256 secret <Password>**. If you set a lower encryption level, the guest user will not be able to authenticate.

5. Create a AAA attribute list to apply QoS profiles on the guest user account.

   Example

   ```
   Device(config-user-name)# aaa attribute list aaa-attribute-list-name
   ```

6. Return to the global configuration mode.

Example

```
Device(config-user-name)# exit
```

Note

If the lobby admin is local, enter this command:

```
aaa authentication login default local
```

If the lobby admin is a remote user, enter these commands:

```
aaa authentication login default group radius/tacacs
```

```
aaa remote username <remote-lobby-admin-name>
```

In case of local or remote lobby, enter this command to map the authorization policies:

```
aaa authorization exec default local
```

Verify guest user account

This section lists the commands and output fields for verifying guest user accounts using the CLI.

```
Device# show aaa local guest_user all

User-Name           : new4
Type                :  GUEST USER
Password            : *
Is_passwd_encrypted : No
Attribute-List      : Not-Configured
Viewname            : Not-Configured
Lobby Admin Name    : NEW_LOBBY_ADMIN
Max Login Limit     : 0
Description         : guest
Start-Time          : 07:56:39 IST Jan 25 2019
Lifetime            : 1 years 0 months 0 days 0 hours 0 mins 0 secs
Expiry-Time         : 07:56:39 IST Jan 20 2020 Remaining Lifetime  : 0 years
11 months 29 days 22 hours 52 mins 49 secs
```

To verify a specific guest user account, use this command:

```
Device# show aaa local guest_user new_guest3

User-Name           : new_guest3
Type                :  GUEST USER
Password            : *
Is_passwd_encrypted : No
```

```
Attribute-List      : Not-Configured
Viewname            : Not-Configured
Lobby Admin Name    : INVALID_ADMIN
Max Login Limit     : 9
Description         : new
Start-Time          : 04:39:01 IST Feb 4 2019
Lifetime            : 1 years 0 months 0 days 0 hours 0 mins 0 secs
Expiry-Time         : 04:39:01 IST Jan 30 2020
Remaining Lifetime  : 0 years 11 months 11 days 21 hours 16 mins 34 secs
```

Assign username to guest users in a WLAN (CLI)

Use this procedure to assign a unique username to a guest user for a specific WLAN profile using commands.

Identify and authenticate guest devices on a WLAN by assigning usernames bound to their MAC addresses using commands.

Before you begin

- If a WLAN profile name is configured for a user, guest user authentication is allowed only from that WLAN.
- If a WLAN profile name is not configured for a user, guest user authentication is allowed on any WLAN.
- To operate in connected mode, configure the AAA policy override under both SSID policies before you assign a username to a guest user on a WLAN.

Procedure

1. Enter the configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Assign a username to the WLAN profile.

   Example

   ```
   Device# username user_name mac wlan-profile-name profile_name
   ```

   Note

   The wlan-profile-name per user is applicable for MAC type users.

3. Display the values of the WLAN profile.

   Example

   ```
   Device# show aaa local guest_user new_guest3
   ```

4. Return to the privileged EXEC mode.

Example

```
Device# end
```

73 Link Local Bridging

Topics:

- Link local bridging

Link local bridging

Introduces Link Local Bridging, explaining how it enables roaming wireless clients to access local services at their point of attachment, maintains VLAN continuity across intra- and inter-controller roaming, and describes its feature history and use cases for enhanced local service discovery.

Link local bridging is a wireless networking mechanism that

- allows roaming wireless clients to use local services at their current point of attachment (PoA)
- preserves access VLAN continuity during intra-controller and inter-controller roaming, and
- reduces the need to tunnel client packets to their original anchor controller.

Feature history

Table 82: Feature history for link local bridging

Feature	Release	Feature Information
Link Local Bridging	Cisco IOS XE 17.6.1	The Link Local Bridging feature allows you to manage link-local traffic in intercontroller and intracontroller roaming scenarios. In Cisco IOS XE Bengaluru 17.5.x and earlier releases, only mDNS multicast link-local frames are forwarded.

Intra-controller and inter-controller roaming scenario

In Cisco IOS XE 17.5.1 and earlier releases, client packets were forwarded through the access VLAN of a client. The client also received all the IPv4 packets or all the IPv6 packets from its assigned access VLAN.

When an L3 client roamed from one controller to another controller, the point-of-presence (PoP) remained with the first controller, also known as the anchor controller or the home controller, and the point-of-attachment (PoA) moved to the second controller, also known as the foreign controller or the visited controller. In this anchor-foreign scenario, the client packets were tunneled back to the anchor controller to be forwarded on the access VLAN of the client.

Similarly, in case of L3 intra-controller roaming, when the feature Roaming Across Policy Profile is enabled, the client access VLAN is maintained, regardless of the policy profile VLAN. In such a scenario, the PoA becomes the destination policy profile VLAN.

A roaming wireless client benefits more from local services available near its PoA than from discovering services at its PoP.

Therefore, from Cisco IOS XE 17.6.1 onward, you can manage these intra-controller and inter-controller roaming scenarios with the Link Local Bridging feature. Link Local Bridging is disabled by default.

Use case

Enhancing Local Service Discovery for Roaming Clients with Link Local Bridging: If you use a local mode deployment and L3 roaming to manage clients moving across different physical locations, the Link Local Bridging feature allows wireless clients to discover nearby services, such as those advertised through mDNS, that are physically close to them. This ensures that, even as clients roam across subnets, they can still find and access local network services in their immediate vicinity.

Guidelines and restrictions for link local bridging

Link Local Bridging guidelines and restrictions.

- The Link Local Bridging feature is supported in local mode or FlexConnect central switching.
- Only mDNS bridge mode is supported with Link Local Bridging.
- Guest profiles are not supported.
- Wired Guest LAN, Remote LAN (RLAN), and Inter-Release Controller Mobility (IRCM) are not supported.
- Mesh and IP Source Guard (IPSG) are not supported when the Link Local Bridging feature is enabled.
- Enable Link Local Bridging on both the anchor and foreign controllers to support roaming.
- Access VLAN and bridge VLAN must be operational to ensure the Link Local Bridging feature functions properly.
- Enable Link Local Bridging on all policy profiles that use the same SSID.
- Configure wireless multicast-over-multicast (**wireless multicast** *multicast IP address*) before enabling the Link Local Bridging feature. The **wireless multicast link-local** command is enabled by default when wireless multicast is enabled.

Enable link local bridging per policy profile (GUI)

Enable Link Local Bridging Per Policy Profile using GUI.

Enable link local traffic bridging for network policy profile using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**
2. Click **Add**.

   The **Add Policy Profile** page is displayed.
3. In the **Add Policy Profile** page, under the **General** tab, enter the name of the policy profile.
4. In the **Advanced** tab, check the **Link-Local Bridging** check box to enable link-local bridging on the policy profile.
5. Click **Apply to Device**.

The device configuration applies the policy profile with link-local bridging enabled.

Enable link local bridging per policy profile (CLI)

Enable Link Local Bridging Per Policy Profile using commands.

Enable link local bridging for wireless clients by configuring a policy profile on the device.

Before you begin

Ensure that both wireless multicast-over-multicast and wireless multicast link-local settings are enabled.

> **Note**
>
> In Cisco IOS XE Bengaluru 17.6.1 and later releases, the wireless multicast link-local setting is enabled by default when multicast is enabled. All downstream multicast link-local frames are forwarded to wireless clients. In Cisco IOS XE Bengaluru 17.5.x and earlier releases, only mDNS multicast link-local frames are forwarded.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create policy profile for the WLAN.

   Example

   ```
   Device(config)# wireless profile policy wireless-profile-name
   ```

3. Enable link-local bridging for the policy profile.

   Example

   ```
   Device(config-wireless-policy)# link-local-bridging
   ```

Link-local bridging is enabled for the specified policy profile.

```
Device# configure terminal
Device(config)# wireless profile policy wireless-profile1
Device(config-wireless-policy)# link-local-bridging
```

Verify link local bridging

Verify Link Local Bridging configurations.

To verify the configuration status of Link Local Bridging, use this command:

```
Device# show wireless profile policy detailed policy1
Policy Profile Name                 : policy1
Description                         :
Status                              : ENABLED
VLAN                                : 81
Multicast VLAN                      : 0
OSEN client VLAN                    :
Multicast Filter                    : DISABLED
QBSS Load                           : ENABLED
Passive Client                      : DISABLED
ET-Analytics                        : DISABLED
StaticIP Mobility                   : DISABLED
```

```
WLAN Switching Policy
  Flex Central Switching            : ENABLED
  Flex Central Authentication       : ENABLED
  Flex Central DHCP                 : ENABLED
  Flex NAT PAT                      : DISABLED
.
.
.
  ----------------------------------------------------
mDNS Gateway
  mDNS Service Policy name          : default-mdns-service-policy
User Defined (Private) Network              : Disabled
User Defined (Private) Network Unicast Drop  : Disabled
Policy Proxy Settings
  ARP Proxy State                   : DISABLED
  IPv6 Proxy State                  : None
Airtime-fairness Profile
  2.4Ghz ATF Policy                 : default-atf-policy
  5Ghz ATF Policy                   : default-atf-policy
Link-local bridging                 : ENABLED
```

To verify if Link Local Bridging VLAN is included, use this command:

```
Device# show wireless client mac 7xxx.3xxx.3xxx detail
Client MAC Address : 7xxx.3xxx.3xxx
.
.
.
Link-local bridging VLAN: 3
.
.
.
WiFi Direct Capabilities:
  WiFi Direct Capable           : No
```

To verify if link local multicast traffic is enabled, use this command:

```
Device# show wireless multicast
Multicast                               : Disabled
AP Capwap Multicast                     : Unicast
Wireless Broadcast                      : Disabled
Wireless Multicast non-ip-mcast         : Disabled
Wireless Multicast link-local           : Enabled
```

74 Web Admin Settings

Topics:

- Web admin settings

This chapter guides administrators through configuring web-based management: enabling HTTP/HTTPS and PIV authentication, installing CA trustpoints, enabling NETCONF/YANG, setting session timeouts, and managing VTY lines and access protocols for secure remote administration.

Web admin settings

Explains the configuration options and roles of web admin settings, which control access and management of a controller's web interface.

A web admin setting is a controller management configuration that

- determines how administrators access the controller's web interface
- specifies the protocols and interfaces available for remote management, and
- enables customization of user access, source interfaces, and file transfer protocols.

These tasks include setting up the controller for communication with other devices in the network and configuring the management interface to connect over IP.

Use the **Administration** > **Management** > **HTTP/HTTPS/Netconf/VTY** page to configure system-wide settings.

Configure HTTP/HTTPS access (GUI)

Use this task to enable and configure HTTP, HTTPS, and Personal Identity Verification (PIV) access for secure web management of your controller.

Securely grant users access to the controller's WebUI using HTTP, HTTPS, and two-factor authentication with PIV smart cards.

HTTP or HTTPS access allows users to access the controller's WebUI using its IP address. You can allow users to connect securely over HTTPS or over HTTP, which is not a secure connection.

Use the **Administration** > **Management** > **HTTP/HTTPs/Netconf/VTY** page to configure secure access to the controller.

Before you begin

- Ensure you have administrator privileges to configure the controller.
- Obtain the CA-signed server certificate and trustpoint configuration if you are enabling PIV authentication.
- Collect the client certificate signed by your CA for browsers using PIV.

Procedure

1. Enable **HTTP Access** then enter the port number for HTTP requests. The default port is 80, but you can also use port 80 or any value from 1025 to 65535.
2. Enable **HTTPS Access** on the device and enter the designated port to listen for HTTPS requests. The default port is 1025. You may use port 443 or any port between 1025 and 65535.

   Enabling HTTPS access allows users to access the controller's GUI using "https://ip-address". On a secure HTTPS connection, data to and from an HTTPS server is encrypted before being sent over the Internet. SSL encryption provides a secure connection for tasks such as configuring a switch from a web browser.
3. Enable Personal Identity Verification (PIV) for two-factor authentication.

   This method lets users access the WebUI with PIV-compatible smart cards, enabling login without a password. To use this authentication method, configure the trustpoint and CA server certificate on the device. Also, ensure that the browser has the client certificate signed by the CA server. If you do not provide the client certificate, access to the UI is denied.
4. Set the **Personal Identity Verification Authorization only** option to *Enabled*. This authorizes a user's permissions and restrictions based on a remote TACACS+ or RADIUS security server.

5. Click **Apply** to save the configuration.

> **Note**
>
> To use Personal Identity Verification (PIV) for two-factor authentication on Safari, perform these steps:
>
> a. Open Safari browser and go to **Settings > Advanced**
>
> 1. Check the **Show Develop in menu bar** check box. This enables the Develop option in the top menu bar.
> 2. Click **Develop**, and from the dropdown, select **Empty Caches**.
>
> b. Open the web url to login.

Configure HTTP trust point (GUI)

Learn how to configure an HTTP trust point to secure web administration on your device using a certificate authority (CA) trustpoint.

Use Secure HTTP (HTTPS) web administration on your device with a CA-signed certificate instead of a self-signed certificate.

Certificate authorities (CAs) manage certificate requests and issue certificates to participating network devices. These services provide centralized security key and certificate management for the participating devices. Specific CA servers are referred to as trustpoints. When a connection attempt is made, the HTTPS server provides a secure connection by issuing a certified X.509v3 certificate, obtained from a specified CA trustpoint, to the client. The client (usually a Web browser), in turn, has a public key that allows it to authenticate the certificate. For secure HTTP connections, we highly recommend that you configure a CA trustpoint. If a CA trustpoint is not configured for the device running the HTTPS server, the server certifies itself and generates the needed RSA key pair. Because a self-certified (self-signed) certificate does not provide adequate security, the connecting client generates a notification that the certificate is self-certified, and the user has the opportunity to accept or reject the connection. This option is useful for internal network topologies (such as testing).

If you do not configure a CA trustpoint and then enable a secure HTTP connection, the device automatically generates either a temporary or a persistent self-signed certificate for the secure HTTP server or client. If the device is not configured with a hostname and domain name, it generates a temporary self-signed certificate. If the switch reboots, it deletes any temporary self-signed certificate and assigns a new one. If the device has been configured with a hostname and domain name, it generates a persistent self-signed certificate. This certificate remains active if you reboot the device or disable the secure HTTP server. The certificate will be available when you re-enable a secure HTTP connection.

Use the **Trust Point Configuration** section of the **Administration** > **Management** > **HTTP/HTTPs/Netconf/VTY** page to make these changes.

Before you begin

You must have configured a trustpoint for web administration purposes.

Procedure

1. Tap to enable the trust point.
2. Select the appropriate trust point from the drop-down list to use for web administration purposes.

   If you have not configured a trust point earlier, you can navigate to the appropriate page and first configure it.

3. Click **Apply** to save the configuration.

Configure NETCONF YANG (GUI)

Use this task to configure NETCONF YANG access on your device through the GUI, including authentication and port settings.

Configure and enable NETCONF YANG to allow programmatic network management and device configuration using commands.

NETCONF provides a mechanism to install, manipulate, or delete the configuration of network devices.

If the NETCONF connection is configured to use AAA for authentication purposes, it uses only the default method list and cannot be pointed to use any other named method list.

Use the **Netconf Yang Configuration** section of the **Administration** > **Management** > **HTTP/HTTPs/Netconf/VTY** page to make these changes.

Procedure

1. Enable NETCONF.
2. Enter the SSH port number that will be used to facilitate communication between a client and a server. The default port is 830.
3. Click **Apply** to save the configuration.

Configure timeout policy (GUI)

Use this task to set session timeout limits for management connections, including HTTP, session idle, and server lifetime policies, to control how long sessions remain active before requiring reauthentication.

Define the duration a management session can remain idle or active before automatic closure. This improves security and resource management.

The Timeout Policy Configuration allows you to set the idle interval for management sessions. Once the timeout is reached, you must log in again to reestablish the connection.

Use the **Timeout Policy Configuration** section of the **Administration** > **Management** > **HTTP/HTTPs/Netconf/VTY** page to make these changes.

Procedure

1. Enter the maximum number of seconds a connection to the HTTP server remains open before timing out in the **HTTP Timeout-policy** field. Once the time value is reached, you must log in again to reestablish the connection.
2. In the **Session Idle Timeout** field, enter the maximum number of seconds the connection remains open if no data is received or if response data cannot be sent.

   Note that this value may not affect already existing connections. If the server is too busy, or if the limit on the life time or number of requests is reached, the connection may close sooner. The default value is 180 seconds (three minutes).

3. In the **Server Life Time** field, enter the maximum number of seconds the connection remains open from when the connection is established.

   Note that the new value might not affect existing connections. If the server is too busy or if the limit on idle time or number of requests is reached, the server may close the connection sooner. The server does not close the connection while actively processing a request. Therefore, the connection might remain open longer than the specified lifetime

if processing continues when the limit is reached. In this situation, the connection will close after processing finishes. The default value is 180 seconds (three minutes). The maximum value is 86400 seconds (24 hours).

4. Enter a value for the maximum limit on the number of requests processed on a persistent connection before it is closed in the **Max Number of Requests** field.

   Note that the new value might not affect existing connections. If the server is too busy, or if the limit on idle time or life time is reached, the connection may close before the maximum number of requests are processed. The default value is one. The maximum value is 86400.

5. Click **Apply** to save the configuration.

Configure VTY (GUI)

Use this task to configure Virtual Terminal (VTY) lines for secure remote access (SSH or Telnet) to your device using the web interface.

Configure the number of simultaneous remote CLI connections and apply security policies to inbound device sessions.

VTY is a virtual port that supports Telnet or SSH access for inbound device connections. You can configure the number of simultaneous connections to your device and add security to validate these connections.

Use the **VTY** section of the **Administration** > **Management** > **HTTP/HTTPs/Netconf/VTY** page to make these changes.

Procedure

1. Set the number of VTY lines to specify how many users can access the device remotely at the same time.

   Virtual Terminal Lines, also called Virtual TeleType (VTY), provide remote access to the controller's CLI without the need to physically connect a laptop to the controller console. The number of VTY lines determines the maximum number of simultaneous connections allowed. Setting the number to a value between zero and 50 allows up to fifty simultaneous Telnet or SSH sessions to the controller. The default is set at 15. We recommend increasing the number of VTY lines to 50 to prevent connectivity disruptions when multiple users access the device.

2. Select the protocol for the remote connection from the **VTY Transport Mode** drop-down list. You can split the connections based on protocol. For example, lines zero to five might allow SSH connections, and lines 10 to 20 might allow Telnet connections.
3. Optional: You can add security in the WebUI to validate login requests. To configure AAA authentication and authorization for inbound sessions to VTY lines on your system, first configure a RADIUS or TACACS+ authentication server. Then, select the authentication and authorization list from the appropriate drop-down menus.
4. Click **Apply** to save the configuration.

Post-quantum cryptography support

Post-quantum cryptography (PQC) support is a security enhancement for web server applications, such as Nginx that

- enables quantum-resistant key exchange within TLS 1.3
- protects data against "harvest now, decrypt later" attacks, and
- maintains backward compatibility with legacy clients using classical cryptographic algorithms.

Quantum-resistant security provides future-proof protection for enterprise and government communications by integrating schemes like ML-KEM into the TLS handshake process. ML-KEM reduces exposure to harvest-now-decrypt-later attacks, in which an attacker stores encrypted traffic for possible decryption by a future quantum computer.

As legacy TLS protocols cannot negotiate post-quantum cryptography (PQC) cipher suites, they remain vulnerable to future decryption threats. This feature allows web servers to deploy quantum-resistant algorithms, such as ML-KEM, alongside traditional cryptographic methods. In non-FIPS environments, the system supports a wide range of PQC, hybrid, and classic groups. In FIPS-compliant environments, PQC-only groups are disabled, and only specific hybrid and classical groups are permitted to ensure regulatory compliance.

Supported key-exchange groups

Non-FIPS mode

These PQC-only groups are supported:

- `mlkem512`
- `mlkem768`
- `mlkem1024`

These hybrid groups are supported:

- `p256_mlkem512`
- `p384_mlkem768`
- `p521_mlkem1024`
- `x25519_mlkem512`
- `x448_mlkem768`
- `X25519MLKEM768`
- `SecP256r1MLKEM768`
- `SecP384r1MLKEM1024`

The classical groups are:

- `P-256`
- `P-384`
- `P-521`

By default, the Nginx web server offers all supported PQC-only, hybrid, and classical groups.

FIPS mode

PQC-only groups are not supported in FIPS mode. These hybrid groups are supported:

- `p256_mlkem512`
- `p384_mlkem768`

The complete group set supported in FIPS mode is:

- `p256_mlkem512`
- `p384_mlkem768`
- `P-256`
- `P-384`

- `P-521`

PQC restrictions

While Post-Quantum Cryptography (PQC) provides enhanced security against future quantum threats, you must account for these limitations and requirements when deploying this feature:

- PQC key exchange groups are supported exclusively within **TLS 1.3**. Applications or clients restricted to TLS 1.2 or older cannot utilize PQC key exchange and will continue to use classic groups.
- PQC-only groups (such as `mlkem512`, `mlkem768`, `mlkem1024`) are not supported in FIPS mode.
- In FIPS mode, only a subset of hybrid groups (`p256_mlkem512`, `p384_mlkem768`) and specific classical groups (`P-256`, `P-384`, `P-521`) are allowed.
- Successful negotiation of PQC or hybrid key exchange requires both the client and the server to be PQC-compliant. If the client does not support these algorithms, the connection will fall back to classical groups.
- Initial TLS handshakes may experience increased latency due to the additional computational complexity of PQC algorithms like ML-KEM.
- In high-frequency connection scenarios, total connection throughput may be impacted, particularly on hardware with limited resources.
- This feature applies to web server applications (for example, WebUI). Other TLS-based applications, such as Web-auth, are not impacted by these PQC configurations.

Configure post-quantum cryptography support (CLI)

Provides instructions for enabling or disabling PQC algorithms on web servers using the CLI, including selecting between all, hybrid, non-PQC, and PQC types to set the cryptographic security level for TLS 1.3 connections.

Enable or disable Post-Quantum Cryptographic (PQC) algorithms for web server applications.

Use this task to define the cryptographic security level for web traffic. By default, the system supports all algorithms, including PQC, hybrid, and classic groups.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the PQC type for the HTTPS server.

   Example

   ```
   Device(config)# ip http secure-pqc-type {all | hybrid | non-pqc | pqc}
   ```

   The PQC types include:

   - **all**: Specifies that all PQC, non-PQC, and hybrid algorithms are supported.
   - **hybrid**: Specifies that the supported type is hybrid cryptographic algorithms (Key derived with PQC and non-PQC).
   - **non-pqc**: Specifies that the supported type is classic cryptographic algorithms.

- **pqc**: Specifies that the supported type is post-quantum cryptographic algorithms.

3. Exit global configuration mode.

Example

```
Device(config)# exit
```

The web server updates its security configuration to use the selected cryptographic algorithms for TLS 1.3 connections.

Verify secure key-exchange configuration

Confirm the current status and enabled cryptographic groups for the secure web server.

To validate your PQC configuration is active and to identify which algorithms are currently supported by the server, use this command:

```
Device# show ip http server secure status
HTTP secure server status:
 HTTP secure server ECDHE curve: secp384r1
 HTTP secure server PQC type: all
```

75 Web UI Configuration Command Accounting in TACACS Server

Topics:

- Web UI configuration command accounting in TACACS+ server

This chapter explains how to configure TACACS+ accounting for controller web UI configuration changes, showing CLI steps to enable AAA command accounting (default and HTTP named method lists) for centralized audit logging.

Web UI configuration command accounting in TACACS+ server

Explains how Web UI configuration command audits enable traceability and accountability for configuration changes made through the controller GUI, by logging these changes to a TACACS+ server.

A Web UI configuration command audit is a security feature that

- records configuration changes executed through the controller's GUI
- logs audit information to a TACACS+ server for centralized tracking, and
- includes details such as the executed command, the user responsible, and session parameters.

The Cisco Catalyst 9800 series wireless controller configuration is stored in databases.

Feature history for Web UI configuration command accounting in TACACS+ server

Web UI Configuration Command Accounting in TACACS+ Server feature history details.

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 83: Feature history for Web UI configuration command accounting in TACACS+ server

Release	Feature	Feature Information
Cisco IOS XE Cupertino 17.9.1	Logging Web UI-Based Configuration Changes in TACACS+ Server	This feature logs all configuration changes made in controller web UI. Support for logging configurations done in IOS console in TACACS+ server is already available.

Guidelines for Web UI configuration command accounting in TACACS+ server

This topic outlines the best practices for enabling and managing configuration command accounting for Web UI sessions in a TACACS+ server environment.

- By default, configuration commands are not logged to the TACACS+ server unless command accounting is configured.
- All commands are accounted for only when AAA default command accounting is configured for privilege level 15.
- If AAA default command accounting is not configured, and you want commands to be logged to the TACACS+ server, use these methods:
  1. The HTTP named method list command accounting.
  2. The AAA named method list (same as the one configured in **Step 1**) command accounting.

Configure AAA accounting using default method list (CLI)

Use this task to enable and configure AAA command accounting to monitor and record user command activity using the default method list on your device.

Use this task to monitor and record user command activity on devices through AAA accounting features.

Configure AAA accounting to track user commands executed on a controller, leveraging the default accounting method. This supports compliance and security needs.

Before you begin

- Confirm that AAA is enabled on the device.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create an accounting method list and enables accounting.

   Example

   ```
   Device(config)# aaa accounting commands 15 default start-stop group group-name
   ```

   - *privilege_level*: AAA accounting level. The valid range is from zero to 15.
   - *group-name*: AAA accounting group that supports only TACACS+ group.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The controller records user command activities according to the configured accounting method.

Configure HTTP command accounting using named method list (CLI)

Use this task to configure HTTP command accounting on your device, allowing you to monitor and record user command activity with AAA features using a named method list.

Set up command accounting to track user actions on network devices via HTTP with a specified AAA method list using commands.

HTTP command accounting provides auditing and compliance by recording commands executed by users. Using a named method list offers flexibility for different accounting requirements.

Before you begin

- Ensure AAA accounting is enabled on your device.
- Have a predefined AAA accounting method list (if not, configure one).

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure HTTP command accounting using the named method list.

   Example

   ```
   Device(config)# ip http accounting commands 1 oneacct
   ```

   - *level*: The privilege value ranges from zero to 15. By default, the command privilege levels available on the controller are:
     - *0*: Includes the **disable**, **enable**, **exit**, **help**, and **logout** commands.
     - *1*: Includes all the user-level commands at the controller prompt (>).
     - *15*: Includes all the enable-level commands at the controller prompt (>).
   - *named-accounting-method-list*: Name of the predefined command accounting method list.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device records user command activities in accordance with the configured accounting method.

76 Embedded Packet Capture

Topics:

- Embedded packet capture

This chapter explains how to configure and verify this troubleshooting feature on Cisco IOS XE Dublin 17.12.1, including increased buffers, continuous captures, filtering multiple inner MAC addresses, and exporting capture files for analysis.

Embedded packet capture

Explains embedded packet capture as a feature for troubleshooting and monitoring network packet flows directly on Cisco devices.

An embedded packet capture is a network troubleshooting feature that

- enables administrators to trace and analyze data packets in real time
- allows capture of packets flowing through, to, and from a Cisco device, and
- supports filtering, buffer management, and packet analysis for diagnosing complex network issues.

The Embedded Packet Capture on the controller is used for troubleshooting multiple issues, such as authentication failures with RADIUS, AP joining or disconnection, client forwarding, disconnection, and roaming. It can also help with specific features, including multicast, mDNS, Umbrella, and mobility. When troubleshooting an AP join or client onboarding issue, you might lose important information if you are unable to stop the capture immediately when the issue occurs. In most cases, a buffer of 100 MB is not sufficient for data capture. Moreover, the existing Embedded Packet Capture feature supports only the filtering of one inner MAC address, which captures the traffic of a specific client. At times, it is difficult to pinpoint which wireless client is experiencing an issue.

Beginning with Cisco IOS XE Dublin 17.12.1, the Embedded Packet Capture feature supports increased buffer size, continuous capture, and filtering of multiple MAC addresses in one session. You cannot configure the Embedded Packet Capture enhancement using the GUI.

Feature history for embedded packet capture

Embedded Packet Capture feature history details.

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 84: Feature history for embedded packet capture

Release	Feature	Feature Information
Cisco IOS XE Dublin 17.12.1	Embedded Packet Capture	The embedded packet capture feature is enhanced to support increased buffer size, continuous capture, and filtering of multiple MAC addresses in one embedded packet capture (EPC) session.

Configure embedded packet capture (CLI)

Use this procedure to configure embedded packet capture (EPC) using CLI commands, enabling you to capture, filter, and export network packet data for analysis.

Configure and manage embedded packet capture on your Cisco device using commands to analyze live packet traffic and gather data for troubleshooting.

With the Embedded Packet Capture feature enhancement, the buffer size is increased from 100 MB to 500 MB.

> **Note**
>
> Buffer is of memory type. You can either maintain a memory buffer or copy the memory buffer that is present in a file to store more information.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

   Enter your password, if prompted.

2. Configure the Gigabit Ethernet interface for inbound, outbound, or both inbound and outbound packets.

   Example

   ```
   Device# monitor capture epc_session-name interface GigabitEthernet
   interface-number {both | in | out}
   ```

   For Cisco 9800-CL controllers, use Gigabit interfaces such as Gi1, Gi2, or Gi3. For physical controllers, specify the port channel if one is configured. Supported physical interfaces include Te or Tw.

   > **Note**
   >
   > To capture packets punted to the CPU, run the **control-plane** command.

3. Optional: Configure monitor capture limit, in seconds.

   Example

   ```
   Device# monitor capture epc_session-name limit duration limit-duration
   ```

4. Optional: Configures the file in circular buffer. (The buffer can be circular or linear.)

   Example

   ```
   Device# monitor capture epc_session-name buffer circular file no-of-files
   file-size per-file-size
   ```

   When **circular** is configured, the files work as a ring buffer. The value range of the number of files to be configured is from two to five. The file size can range from 1 MB to 500 MB.

   The **buffer** command supports various keywords, such as **circular** , **file** , and **size**. The **circular** command is optional.

> **Note**
>
> A circular buffer is required for continuous capture.
>
> This step generates swap files on the controller. Swap files are not packet capture (PCAP) files and cannot be analyzed directly. When you run the **export** command, the swap files are combined and exported as one PCAP file.

5. Configure inline filters and configure a monitor capture specifying an access list as the filter for the packet capture.

   Example

   ```
   Device# monitor capture epc_session-name match {any | ipv4 | ipv6 | mac |
   pklen-range}
   ```

   ```
   Device# monitor capture epc_session-name access-list access-list-name
   ```

   > **Note**
   >
   > You can configure filters and ACLs.

6. Optional: Configure continuous packet capture.

   Example

   ```
   Device# monitor capture epc_session-name continuous-capture http:
   location/filename
   ```

   Enable the automatic export of files to a specific location before the buffer is overwritten.

   > **Note**
   >
   > - A circular buffer is required for continuous capture.
   > - Configure the filename with a .pcap extension.
   > - An example of the filename and nomenclature used to generate the filename is as follows:
   >   CONTINUOUS_CAP_20230601130203.pcap
   >
   >   CONTINUOUS_CAP_20230601130240.pcap
   > - After packets are exported automatically, the buffer is not cleared until it is overwritten by new incoming capture packets, cleared, or deleted using commands.

7. Optional: Configure up to 10 MAC addresses as inner MAC filter.

Example

```
Device# monitor capture epc_session-name inner mac [ MAC1 | MAC2 |
MAC3......... ]
```

```
Device# no monitor capture epc_session-name inner mac [ MAC1 | MAC2 |
MAC3......... ]
```

Note

- You cannot modify the inner MAC addresses while the capture is in progress.
- You can enter the MAC addresses in a single command or over multiple command lines. Because of the character string limitation, you can enter only five MAC addresses in a single command line. To enter the remaining MAC addresses, use the next command line.
- If you have configured 10 inner MAC addresses, you must delete an existing address before adding a new one.

8. Start capture of packet data and stop capture of packet data.

Example

```
Device# no monitor capture epc_session-name start
```

```
Device# no monitor capture epc_session-name stop
```

9. Export captured data for analysis when continuous capture is not configured.

Example

```
Device# monitor capture epc_session-name export filelocation/filename
```

Verify embedded packet capture

This section lists the commands and output fields relevant to verifying embedded packet capture (EPC) status, configuration, and buffer contents on a device.

To view the configured file number and per file size, run this command:

Note

This command is displayed irrespective of whether continuous capture is enabled or not. The configured inner MAC addresses are also displayed using this command.

```
Device# show monitor capture epc_session1
Status Information for Capture epc_session1
  Target Type:
 Interface: TwoGigabitEthernet0/0/0, Direction: BOTH
   Status : Inactive
  Filter Details:
    Capture all packets
                Inner Filter Details:
                Continuous capture: enabled
                Continuous capture path:
                 ftp://mgcusr:mgcusr@10.124.19.169//home/mgcusr/xij/repo.pcap

               Buffer Details: Buffer Type: CIRCULAR No of files: 5 File Size
 (in MB): 21
  Limit Details:
   Number of Packets to capture: 0 (no limit)
   Packet Capture duration: 3600
   Packet Size to capture: 0 (no limit)
   Maximum number of packets to capture per second: 1000
   Packet sampling rate: 0 (no sampling)
```

To view the configured Embedded Packet Capture buffer files, run these commands:

```
Device# show monitor capture epc_session1 buffer brief
 ----------------------------------------------------------------------------

 #   size   timestamp     source             destination      dscp    protocol

 ----------------------------------------------------------------------------

   0 1386    0.000000   192.168.10.117   ->  192.168.10.100   0  BE   UDP
   1 1378    0.000000   192.168.10.100   ->  192.168.10.117   0  BE   UDP
   2 1386    0.001007   192.168.10.117   ->  192.168.10.100   0  BE   UDP
```

Note

This command works for normal embedded packet capture (EPC) but is not supported in continuous captures.

```
Device# show monitor capture epc_session1 buffer dump

77 Layer 3 Access

Topics:

- Layer 3 access
- OSPF protocols
- PIM sparse mode
- Network address translation (NAT)

This chapter explains configuring Layer 3 wireless controller deployments on Cisco Catalyst 9800 series, covering L3 access setup, OSPF and PIM multicast integration, DHCP/NAT with VRF, and verification commands.

Layer 3 access

Explains Layer 3 access and how it enables routing and advanced networking features on Cisco Catalyst 9800 series wireless controllers.

A Layer 3 access is a wireless controller deployment mode that

- terminates wireless client subnets directly on the controller
- supports Layer 3 routing functions such as OSPFv2 and PIM-SM, and
- enables client subnet segmentation, overlapping IP support, and a scalable network design.

Starting from Cisco IOS XE 17.13.1, the Cisco Catalyst 9800 series wireless controller platforms can be deployed as a Layer 3 (L3) network to perform routing functions.

In Cisco IOS XE 17.12.x and earlier releases, these platforms are deployed as Layer 2 network elements. In these deployments, wireless client subnets are terminated at an upstream network element. Upstream refers to the direction in which data is transferred from clients to a server. The controller forwards traffic based on the MAC address of the clients.

The L3 access feature terminates wireless client subnets in the controller and supports Layer 3 forwarding for wireless client traffic. When L3 is enabled on a specific SSID, the client VLAN of that SSID is terminated at the controller. In this scenario, the wireless controller forwards traffic based on the network layer (IP) address.

This enables:

- Segmentation and client overlapping IP address support using VRF.
- Flexible network design and faster convergence.
- Consistency in network design.
- Scalability for upstream switches and routers.

The core focus is seamless integration of OSPF and multicast routing. This transition empowers wireless networks to respond dynamically to changing business requirements, ensuring optimal performance and agility in dynamic networking environments.

Restrictions for Layer 3 access

This topic outlines the restrictions for Layer 3 access WLANs, including unsupported configurations and features you must avoid to ensure correct operation.

- By default, the L3 access is disabled on a WLAN.
- Only N+1 redundancy is supported with L3 access.
- You cannot configure multiple IP addresses in an SVI.
- High Availability SSO is not supported in L3 WLANs.
- In mixed mode (L2 and L3 WLANs), HA SSO with Loopback as WMI is not supported.
- The **ip radius source-interface vrf** global command is not supported.

- These NAT CLIs are not supported in Cisco IOS XE 17.13.1:

```
show ip nat aggregation
```

```
show ip nat bpa
```

```
show ip nat ha
```

```
show ip nat limits
```

```
show ip nat map
```

```
show ip nat platform
```

```
show ip nat pool
```

```
show ip nat portblock
```

```
show ip nat redundancy
```

```
show ip nat route-dia
```

```
show ip nat translations
```

```
clear ip nat translations
```

- Multicast stream is not supported with VRF.
- Client IPv6 is not supported. The controller or AP cannot have IPv6 addresses.

Use cases for Layer 3 access

This topic outlines the best practices for deploying Layer 3 access, including segmentation, NAT, and support for optimized network designs.

Layer 3 access support

- Segmentation and client overlapping IP address support.
- Flexible and optimized network design using L3 access.

Network Address Translation (NAT) support

- Translating client traffic in the guest network to reach the corporate services (For instance, Cisco ISE).
- Hiding the private IP addresses of clients from outside networks.

> **Note**
>
> Only NAT with IPv4 to IPv4 translation is supported in Cisco IOS XE 17.13.1.

Enable Layer 3 access on policy profile (GUI)

Use this task to enable Layer 3 access on a policy profile so that client traffic on a WLAN can benefit from Layer 3 forwarding.

Enable Layer 3 access on a policy profile to allow client devices connected to the WLAN to utilize Layer 3 forwarding using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Select a policy profile and in the **Edit Policy Profile** window, go to the advanced policy profile properties.
3. Under the **Advanced** tab, enable **L3 Access** on the policy profile so that client traffic on a WLAN that has this policy can benefit from Layer 3 forwarding.
4. Click **Apply to Device**.

Enable Layer 3 access on policy profile (CLI)

Use this task to enable Layer 3 (L3) access for a wireless policy profile using the commands.

Configure a wireless policy profile so that wireless clients can obtain IP addresses and network access through Layer 3 using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a wireless policy profile.

   Example

   ```
   Device(config)# wireless profile policy profile-policy
   ```

3. Disable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Enable L3 access in the wireless policy profile.

Example

```
Device(config-wireless-policy)# l3-access
```

5. Enable the wireless policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

Configure a client gateway (GUI)

Use this procedure to configure a client gateway (SVI interface) and associate it with a VRF using the GUI.

Configure a client gateway by associating an SVI interface with a VRF and enabling Autostate Disable to keep the SVI up regardless of connected port status using the GUI.

Procedure

1. Choose **Configuration** > **Layer2** > **VLAN** and select the **SVI** tab.
2. Click an SVI interface. On the **General** tab of the **Edit SVI** window, select a VRF from the drop-down list to associate it with the SVI interface.
3. Enable the **Autostate Disable** to keep the SVI up, even when all ports on the VLAN are down.
4. Click **Save & Apply to Device**.

Configure a client gateway (CLI)

Use this procedure to configure a client gateway interface with a multiprotocol VRF and static IP address using commands.

Establish a client gateway interface, assign it to a VRF, and configure its operational parameters using the commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Specify an interface and enter the interface configuration mode.

Example

```
Device(config)# interface type number
```

3. Activate multiprotocol VRF in an interface.

Example

```
Device(config-if)# vrf forwarding vrf-name
```

4. Define the IP address for the VRF.

Example

```
Device(config-if)# ip address ip-address mask-address
```

5. Configure SVI to ensure that SVI is up even if the VLAN is not switched out.

Example

```
Device(config-if)# no autostate
```

6. Exit the interface configuration mode and enter the global configuration mode.

Example

```
Device(config-if)# end
```

Enable internal DHCP with VRF (CLI)

Use this task to enable the internal DHCP server with Virtual Routing and Forwarding (VRF) on your wireless network device using commands.

Enable the internal DHCP server on a WLAN with VRF support by configuring the policy profile and related settings using the device commands.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy profile-policy
```

3. Add a description for the policy profile and configure AAA policy override.

Example

```
Device(config-wireless-policy)# description profile-policy-description
```

```
Device(config-wireless-policy)# aaa-override
```

4. Enable DHCP Option 82 for the wireless clients and enable VRF on DHCP Option 82.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp opt82
   ```

   ```
   Device(config-wireless-policy)# ipv4 dhcp opt82 vrf
   ```

5. Configure the WLAN's IPv4 DHCP server IP address and VRF name.

   Example

   ```
   Device(config-wireless-policy)# ipv4 dhcp server ip-address vrf vrf-name
   ```

6. Disable the wireless policy profile and enable L3 access in the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

   ```
   Device(config-wireless-policy)# l3-access
   ```

7. Configure Network Access Control in the policy profile.

   Example

   ```
   Device(config-wireless-policy)# nac
   ```

8. Map the VLAN to a policy profile.

   Example

   ```
   Device(config-wireless-policy)# vlan vlan-id
   ```

   If vlan-id is not specified, the default native vlan 1 is applied. The valid range for *vlan-id* is 1 to 4096.

9. Enable the wireless policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

Verify internal DHCP with VRF details

This section lists commands and sample outputs for verifying internal DHCP and VRF configuration, NAT datapath, and device IP tracking on Cisco devices.

To verify the internal DHCP details, use this command:

```
Device# show run int Vlan55
Building configuration...
Current configuration : 290 bytes
!
interface Vlan55
vrf forwarding sample_guest
ip address 55.55.55.2 255.255.255.0
no ip proxy-arp
ip nat inside
ip cef accounting non-recursive external
ip ospf authentication message-digest
ip ospf message-digest-key 1 md5 cisco123
no autostate
no mop enabled
no mop sysid
end
```

To verify the NAT datapath statistics, use this command:

```
Device# show run int Loopback1
Building configuration...
Current configuration : 90 bytes
!
interface Loopback1
vrf forwarding sample_guest
ip address 7.7.7.1 255.255.255.0
end
ip dhcp pool l3_sample_guest
vrf sample_guest
network 55.55.55.0 255.255.255.0
default-router 55.55.55.2
```

To verify the IP entries from database, use this command:

```
Device# show wireless device-tracking database ip
IP                                          ZONE/VRF-TABLE-ID     STATE
 DISCOVERY     MAC                VRF-NAME
55.55.55.2                                  0x00000003          Reachable
   Local      001e.bd11.a0ff

               55.55.55.6                                     0x00000003
   Reachable      IPv4 DHCP   58a0.239b.d25f     sample_guest
```

Verify Layer 3 access details

This section lists commands and their output fields for verifying Layer 3 access status on policy profiles and clients.

To verify whether Layer 3 access is enabled for a specific policy profile, use this command:

```
Device# show wireless profile policy detailed default-policy-profile
Policy Profile Name                : default-policy-profile
Description                        : default policy profile
Status                             : ENABLED
VLAN                               : 20
.
.
.

                L3 Forwarding
     :ENABLED
```

To view whether the Layer 3 access is enabled under policy profile, use this command:

```
Device# show wireless profile policy all
Policy Profile Name                : default-policy-profile
Description                        : default policy profile
Status                             : ENABLED
VLAN                               : 20
.
.
.

                L3 Forwarding
     :ENABLED
```

To verify the client information, use this command:

```
Device# show wireless client mac-address <mac-address> detail
Client MAC Address : a886.ddb2.05e9
.
.
.

L3 Forwarding: Enabled
```

To verify the client gateway details, use this command:

```
Device# show wireless client mac-address 0024.d742.46e4 detail | inc Gateway
.
.
.

                Client Gateway IPv4 Address : 117.117.117.1
```

> **Note**
>
> The client gateway is displayed only if the client performs DHCP.
>
> If the client learns IP using static or ARP, the client gateway will not be displayed.

OSPF protocols

Explains OSPF protocols, their key functions as link-state routing protocols, core authentication methods, notable features and enhancements in OSPF deployments.

An OSPF protocol is a link-state routing protocol that

- calculates the best path through a network using the shortest path first algorithm
- enables dynamic route selection for IP networks, and
- supports multiple authentication methods for secure device communication.

OSPF is a widely used Interior Gateway Protocol (IGP). Each device can verify the identity of the other devices it communicates with.

OSPF supports several types of authentication:

- Simple password authentication: Each device uses a clear-text password configured for authentication with other devices. However, this method is not secure as the password appears in configuration files and OSPF messages. This is not a secure way to configure devices.
- MD5 authentication: This method uses the MD5 algorithm to compute a hash value from the OSPF packet contents and a password.

> **Note**
>
> Starting with Cisco IOS XE 17.13.1, OSPFv2 and ECMP are supported.

Configure OSPF

Use this task to enable and configure OSPF routing on your device interfaces.

Set up Open Shortest Path First (OSPF) to enable dynamic routing across device interfaces.

Procedure

1. Configure a clear-text password (or) message digest key in an OSPF-enabled interface.
2. Create an OSPF routing process.
3. Specify the range of IP addresses to associate with the routing process.
4. Assign area IDs to be associated with that range.

What to do next

What to do next

> **Note**
>
> To enable OSPF in SVI interfaces, you must enable Multicast over Multicast (MOM) using the **wireless multicast** *ip-address* command. This allows OSPF to establish neighbor adjacencies between SVIs.

These topics describe procedures to configure routing protocol:

Configure OSPF interfaces (GUI)

Use this task to configure OSPF interface settings on a device using the GUI.

Enable and customize OSPF parameters on specific interfaces through the GUI.

Procedure

1. Choose **Configuration** > **Interface** > **Ethernet** and select an interface to configure it with OSPF settings.
2. In the **Configure Interface** window, ensure that you have configured an IP address, subnet mask and optionally a secondary IP address.
3. In the **OSPF** section, enter the **Process ID** to enable OSPF on the interface.
4. Enable the **BFD** to create a Bidirectional Forwarding Detection session between two systems. BFD provides a short-duration method of detecting failures in the forwarding path between two adjacent peers.
5. Select the **Dead Interval Minimal** and enter the number of seconds in the **Hello Multiplier** field to set the interval at which at least one hello packet must be received, or else the neighbor is considered down.
6. Select **Message Digest Authentication** to configure the authentication supported by OSPF.
7. Under the **Message Digest Authentication- Key Map** association box, enter the Key, Type and Password.
8. Click **Save & Apply to Device**.

> **Note**
>
> To configure OSPF in SVI interfaces, you must enable Multicast over Multicast (MOM). This allows OSPF to establish neighbor adjacencies between SVIs.

Configure OSPF protocol (GUI)

Use this task to configure OSPF protocol settings on a router through the GUI.

Configure OSPF protocol for dynamic routing between network devices using the GUI.

Procedure

1. Choose **Configuration** > **Routing Protocol** > **OSPF** and click **Add**.

2. In the **Add Route** page, select the router from the drop-down list.
3. Enter the **Process ID**. It identifies the router's OSPF routing process to other routers.
4. Enter a **Router ID**.
5. Enable the **BFD** to create a Bidirectional Forwarding Detection session between two systems. BFD provides a short-duration method for detecting failures in the forwarding path between two adjacent switches. This includes interfaces, data links, and forwarding planes. OSPF registers as a protocol with BFD and receives forwarding path detection failure messages from BFD. You can configure BFD support for OSPF globally on all interfaces, or selectively on specific interfaces. BFD timers are negotiated. The BFD peers begin sending BFD control packets to each other at the negotiated interval.
6. Enable **NSR** on a router with redundant Route Processors (RPs) so that it maintains its Open Shortest Path First (OSPF) state and adjacencies during both planned and unplanned RP switchovers. The active RP transfers OSPF state information to the standby RP by checkpointing the data. After a switchover to the standby RP, OSPF uses the checkpointed information to continue operation without interruption.

   Optionally, you can check the corresponding check box to enable VRF and select the VRF Name. If you have not configured the VRF, use the link to configure it on the **Interface** > **VRF** page.
7. For advanced options, check the **Advanced** radio button and populate these fields:

   IP Address: Enter the address of the destination network for this route.

   Wildcard: Enter the subnet mask used on that network.

   Area: The OSPF area number for that network. Each router in a particular OSPF area maintains a topological database for that area.
8. Click **Save & Apply to Device**.

Configure basic OSPF parameters (CLI)

Learn how to configure basic OSPF parameters using commands to enable dynamic routing in your network device.

Enable OSPF routing and define key parameters for efficient dynamic route advertisement and network segmentation using commands.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```
2. Enable OSPF routing.

   Example

   ```
   Device(config)# router ospf process-id
   ```

   The *process-id* is an internally used identification parameter that is locally assigned and can be any positive integer. Each OSPF routing process has a unique value.

> **Note**
>
> The OSPF for Routed Access supports a maximum of 1000 dynamically learned routes.

3. Define a network on which the OSPF runs an area ID for that interface.

   Example

   ```
   Device(config-router)# network address wildcard-mask area area-id
   ```

   You can use the *wildcard-mask* to define one or more interfaces to be associated with a specific OSPF area. The *area-id* can be a decimal value or an IP address.

4. Enable Bidirectional Forwarding Detection (BFD) in all interfaces.

   Example

   ```
   Device(config-router)# bfd all-interfaces
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-router)# end
   ```

Configure OSPF interfaces (CLI)

Use this procedure to configure OSPF interfaces using commands for device interfaces that require dynamic routing with OSPF.

Configure router interfaces to participate in OSPF routing, enabling dynamic route exchange within OSPF areas on the network.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify interface to configure OSPF interfaces.

   Example

   ```
   Device(config)# interface GigabitEthernet interface-number
   ```

3. Configure IP address for the OSPF interface.

Example

```
Device(config-if)# ip address ip-address mask-address
```

4. Enable message digest for a specific interface.

Example

```
Device(config-if)# ip ospf authentication message-digest
```

5. Enable message digest key for the OSPF.

Example

```
Device(config-if)# ip ospf authentication message-digest-key key-number md5
password
```

6. Assign interface and its network to OSPF process and area.

Example

```
Device(config-if)# ip ospf value area area-id
```

7. Enable BFD in an interface.

Example

```
Device(config-if)# ip ospf bfd
```

8. Return to privileged EXEC mode.

Example

```
Device(config-if)# end
```

Verify routing protocol details

This section lists common commands to verify routing protocol status and behavior. Each entry describes the command's purpose and summarizes key fields from its output to assist with prompt network troubleshooting.

To verify the OSPF details, use this command:

```
Device# show ip ospf 1
Routing Process "ospf 1" with ID 31.31.31.1
 Start time: 00:01:46.103, Time elapsed: 03:12:34.745
 Supports only single TOS(TOS0) routes
 Supports opaque LSA
 Supports Link-local Signaling (LLS)
 Supports area transit capability
 Supports NSSA (compatible with RFC 3101)
 Supports Database Exchange Summary List Optimization (RFC 5243)
 Event-log enabled, Maximum number of events: 1000, Mode: cyclic
 Router is not originating router-LSAs with maximum metric
```

```
 Initial SPF schedule delay 50 msecs
 Minimum hold time between two consecutive SPFs 200 msecs
 Maximum wait time between two consecutive SPFs 5000 msecs
 Incremental-SPF disabled
 Initial LSA throttle delay 50 msecs
 Minimum hold time for LSA throttle 200 msecs
 Maximum wait time for LSA throttle 5000 msecs
 Minimum LSA arrival 100 msecs
 LSA group pacing timer 240 secs
 Interface flood pacing timer 33 msecs
 Retransmission pacing timer 66 msecs
 EXCHANGE/LOADING adjacency limit: initial 300, process maximum 300
 Number of external LSA 0. Checksum Sum 0x000000
 Number of opaque AS LSA 0. Checksum Sum 0x000000
 Number of DCbitless external and opaque AS LSA 0
 Number of DoNotAge external and opaque AS LSA 0
 Number of areas in this router is 1. 1 normal 0 stub 0 nssa
 Number of areas transit capable is 0
 External flood list length 0
 IETF NSF helper support enabled
 Cisco NSF helper support enabled
 Reference bandwidth unit is 100 mbps
    Area 1
        Number of interfaces in this area is 3
 Area has no authentication

PIM sparse mode

Explains how PIM sparse modes operate as multicast routing protocols, their reliance on explicit group membership, and the role of the Rendezvous Point (RP) in managing group traffic.

A PIM sparse mode is a multicast routing protocol that

- assumes recipients for multicast groups are sparsely distributed throughout the network
- builds multicast distribution trees rooted at a selected Rendezvous Point (RP) node by default, and
- requires routers to explicitly signal interest in specific multicast groups or sources.

Protocol Independent Multicast (PIM) includes multicast routing protocols for various environments.

For information about PIM-SM, see https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipmulti_pim/configuration/15-sy/imc-pim-15-sy-book/ip6-mcast-pim-sm.html.

PIM-SM

Most network subnets do not require every multicast packet. Routers explicitly inform upstream neighbors of their interest in specific multicast groups and sources to receive multicast data.

A key requirement of PIM-SM is discovering the RP address for a multicast group through a shared tree.

Enable multicast traffic without VRF (GUI)

Use this task to enable multicast traffic on your device without configuring a VRF, using the GUI.

Enable multicast routing and required protocols to support multicast traffic delivery in VLANs without VRF using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **Multicast**.
2. In the **PIM and Multicast Routing** section, configure multicast routing globally by enabling **Distributed Multicast-Routing**.
3. Configure PIM RP-Address in the **PIM Configuration** sub-section. This configuration is required so that receivers can find the multicast source in the network. Choose the configuration options from these options:
   - Enter the address to statically configure the RP Address.
   - Enable Auto RP Listener to dynamically discover RP in a PIM-SM network.
4. Click **Save & Apply to Device**.
5. Designate the interface on which multicast traffic should be sent. To do so, go to **Configuration** > **Layer 2** > **VLAN** and select the **SVI** interface.
6. Enable the **PIM Sparse Mode** protocol so that the SVI interface can participate in sparse mode multicast traffic transmission and join the multicast shared tree. This ensures that clients in that VLAN can receive multicast traffic from multiple multicast groups or sources.
7. Select the desired IGMP version from the drop-down list to improve multicast packet direction. When this feature is enabled, the controller gathers IGMP reports from the clients and processes them. It creates unique multicast group IDs (MGIDs) from the IGMP reports by selecting the Layer 3 multicast address and the VLAN number, then sends the IGMP reports to the infrastructure switch.
8. Select **IPv4** checkbox and enter the details.
9. Click **Save & Apply to Device**.

Enable multicast traffic without VRF (CLI)

Use this task to enable multicast traffic on a device without a VRF using commands, including IP multicast routing, PIM, OSPF authentication, and necessary interface configurations.

Enable multicast routing capabilities on a device in a flat (non-VRF) environment and ensure proper configuration for multicast traffic propagation using commands.

Procedure

1. Enter the global configuration mode and enable IP multicast routing.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# ip multicast-routing distributed
   ```

   The **distributed** keyword enables multicast globally.

2. Enable multicast traffic and configure the address of a PIM Rendezvous Point (RP).

   Example

   ```
   Device(config)# wireless multicast ip-address
   ```

   ```
   Device(config)# ip pim rp-address ip-address
   ```

3. Select an interface connected to hosts on which PIM can be enabled.

   Example

   ```
   Device(config)# interface interface-type-number
   ```

4. Add a description for the VLAN.

   Example

   ```
   Device(config-if)# description description
   ```

5. Enable IP address on an interface and disable proxy ARP.

   Example

   ```
   Device(config-if)# ip address ip-address mask-address
   ```

   ```
   Device(config-if)# no ip proxy-arp
   ```

6. Enable PIM-SM mode and enable OSPF authentication for a specific interface.

   Example

   ```
   Device(config-if)# ip pim sparse-mode
   ```

   ```
   Device(config-if)# ip ospf authentication message-digest
   ```

7. Enable message digest key for the OSPF.

   Example

   ```
   Device(config-if)# ip ospf authentication message-digest-key key-number md5
   password
   ```

8. Disable the maintenance operation protocol (MOP) for an interface.

   Example

   ```
   Device(config-if)# no mop enabled
   ```

9. Disable the task of sending MOP periodic system ID messages and return to the privileged EXEC mode.

Example

```
Device(config-if)# no mop sysid
```

```
Device(config-if)# end
```

Enable multicast traffic with PIM-SSM (CLI)

Use this task to enable multicast traffic on your device using Protocol Independent Multicast-Source Specific Multicast (PIM-SSM) using commands.

Enable efficient multicast traffic routing for applications that require directed streaming to specific receivers using commands.

Procedure

1. Enter the global configuration mode and enable IP multicast routing.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# ip multicast-routing distributed
   ```

   The **distributed** keyword enables MDS globally.

2. Enable multicast traffic.

   Example

   ```
   Device(config)# wireless multicast ip address
   ```

   For information about the multicast traffic, see Wireless Multicast.

3. Configure PIM-SSM on all network devices.

   Example

   ```
   Device(config)# ip pim ssm default
   ```

   > **Note**
   >
   > The default SSM range is **232.0.0.0/8**. So, if you do not configure different range, the default SSM range is used.

4. Define SSM range of IP multicast addresses.

Example

```
Device(config)# ip pim ssm range access-list
```

5. Select an interface connected to hosts on which PIM can be enabled.

Example

```
Device(config)# interface interface-type-number
```

6. Add a description for the VLAN.

Example

```
Device(config-if)# description description
```

7. Enable IP address on an interface.

Example

```
Device(config-if)# ip address ip address mask-address
```

8. Disable proxy ARP.

Example

```
Device(config-if)# no ip proxy-arp
```

9. Enable PIM-SM on an interface and return to privileged EXEC mode.

Example

```
Device(config-if)# ip pim sparse-mode
```

```
Device(config-if)# end
```

Verify multicast traffic details

This section lists the main commands and outputs used to verify multicast traffic details, group memberships, IGMP snooping, and troubleshoot multicast issues on Cisco devices.

To verify if a multicast group supports SSM or not, use this command:

```
Device# show ip mroute
IP Multicast Routing Table
Flags: D - Dense, S - Sparse, B - Bidir Group, s - SSM Group, C - Connected,
       L - Local, P - Pruned, R - RP-bit set, F - Register flag,
       T - SPT-bit set, J - Join SPT, M - MSDP created entry, E - Extranet,
       X - Proxy Join Timer Running, A - Candidate for MSDP Advertisement,
       U - URD, I - Received Source Specific Host Report,
       Z - Multicast Tunnel, z - MDT-data group sender,
```

```
       Y - Joined MDT-data group, y - Sending to MDT-data group,
       G - Received BGP C-Mroute, g - Sent BGP C-Mroute,
       N - Received BGP Shared-Tree Prune, n - BGP C-Mroute suppressed,
       Q - Received BGP S-A Route, q - Sent BGP S-A Route,
       V - RD & Vector, v - Vector, p - PIM Joins on route,
       x - VxLAN group, c - PFP-SA cache created entry,
       * - determined by Assert, # - iif-starg configured on rpf intf,
       e - encap-helper tunnel flag, l - LISP decap ref count contributor
Outgoing interface flags: H - Hardware switched, A - Assert winner, p - PIM
Join
                          t - LISP transit group
 Timers: Uptime/Expires
 Interface state: Interface, Next-Hop or VCD, State/Mode
(*, 239.0.0.158), 00:00:07/stopped, RP 15.1.1.2, flags: SJC
  Incoming interface: GigabitEthernet3, RPF nbr 13.1.1.2
  Outgoing interface list:
    Vlan12, Forward/Sparse, 00:00:07/00:02:52, flags:
(17.1.1.1, 239.0.0.158), 00:00:06/00:02:53, flags: JT
  Incoming interface: GigabitEthernet3, RPF nbr 13.1.1.2
  Outgoing interface list:
    Vlan12, Forward/Sparse, 00:00:06/00:02:53, flags:
(*, 231.1.1.1), 02:32:08/stopped, RP 15.1.1.2, flags: SJCF
  Incoming interface: GigabitEthernet3, RPF nbr 13.1.1.2
  Outgoing interface list:
    Vlan12, Forward/Sparse, 00:01:31/00:01:28, flags:
(12.1.0.198, 231.1.1.1), 02:32:08/00:02:53, flags: PFT
  Incoming interface: Vlan12, RPF nbr 0.0.0.0
  Outgoing interface list: Null
(*, 224.0.1.40), 02:32:14/00:02:47, RP 15.1.1.2, flags: SJPL
  Incoming interface: GigabitEthernet3, RPF nbr 13.1.1.2
  Outgoing interface list: Null
```

To verify the IGMP membership details, use this command:

```
Device# show ip igmp membership
Flags: A  - aggregate, T - tracked
       L  - Local, S - static, V - virtual, R - Reported through v3
       I - v3lite, U - Urd, M - SSM (S,G) channel
       1,2,3 - The version of IGMP, the group is in
Channel/Group-Flags:
       / - Filtering entry (Exclude mode (S,G), Include mode (G))
Reporter:
       <mac-or-ip-address> - last reporter if group is not explicitly tracked

       <n>/<m>      - <n> reporter in include mode, <m> reporter in exclude
 Channel/Group                Reporter       Uptime   Exp.  Flags  Interface

 *,239.255.255.250             11.1.1.4        00:01:38 02:57 2A     Vl12
 *,239.0.0.158                 11.1.1.3        00:00:05 02:54 2A     Vl12
 *,231.1.1.1                   12.1.0.8        00:00:07 02:52 2A     Vl12
 *,224.0.1.40                  13.1.1.1        02:34:15 02:45 2LA    Gi3
```

To verify the IGMP snooping details, use this command:

```
Device# show ip igmp snooping igmpv2-tracking
Client to SGV mappings
----------------------
Client: 11.1.1.3 Port: Ca2
    Group: 239.0.0.158 Vlan: 12 Source: 0.0.0.0 blacklisted: no
Client: 11.1.1.4 Port: Ca2
```

```
    Group: 239.255.255.250 Vlan: 12 Source: 0.0.0.0 blacklisted: no
SGV to Client mappings
---------------------
Group: 239.0.0.158 Source: 0.0.0.0 Vlan: 12
    Client: 11.1.1.3 Port: Ca2 Blacklisted: no
Group: 239.255.255.250 Source: 0.0.0.0 Vlan: 12
    Client: 11.1.1.4 Port: Ca2 Blacklisted: no
```

To verify the multicast group summary details, use this command:

```
Device# show wireless multicast group summary
IPv4 groups
-------------
MGID        Group              Vlan
---------------------------------------
4160        239.255.255.250    12
4161        239.255.255.250    12
 IPv6 groups
-------------
MGID        Group                          Vlan
-------------------------------------------------
```

To verify the IGMP snooping groups, use this command:

```
Device# show ip igmp snooping groups
Vlan      Group                Type        Version     Port List
------------------------------------------------------------------------------
12        239.0.0.158          igmp        v2          Ca2
12        239.255.255.250      igmp        v2          Ca2
```

To verify the IGMP snooping, use this command:

```
Device# show ip igmp snooping
Global IGMP Snooping configuration:
-------------------------------------------
IGMP snooping                : Enabled
Global PIM Snooping          : Disabled
IGMPv3 snooping (minimal)    : Enabled
Report suppression           : Enabled
TCN solicit query            : Disabled
TCN flood query count        : 2
Robustness variable          : 2
Last member query count      : 2
Last member query interval   : 1000
.
.
.
Vlan 11:
--------
IGMP snooping                        : Enabled
Pim Snooping                         : Disabled
IGMPv2 immediate leave               : Disabled
Multicast router learning mode       : pim-dvmrp
CGMP interoperability mode           : IGMP_ONLY
Robustness variable                  : 2
Last member query count              : 2
Last member query interval           : 1000
Vlan 12:
```

```
--------
IGMP snooping                        : Enabled
Pim Snooping                         : Disabled
IGMPv2 immediate leave               : Disabled
Multicast router learning mode       : pim-dvmrp
CGMP interoperability mode           : IGMP_ONLY
Robustness variable                  : 2
Last member query count              : 2
Last member query interval           : 1000
```

To verify the active streams from any sources, use this command:

```
Device# show ip mroute active
Active IP Multicast Sources - sending >= 4 kbps
Group: 239.255.0.1, (?)
   Source: 192.168.33.32 (?)
   Rate: 10 pps/115 kbps(1sec), 235 kbps(last 23 secs), 87 kbps(life avg)
```

To verify the TTL related issues in the path for the given stream, use this command:

```
Device# show ip traffic | include bad hop count
0 format errors, 0 checksum errors, 1529 bad hop count
```

To verify the RPF failures, use this command:

```
                Device# show ip mroute count | inc RPF failed|Other
Other counts: Total/RPF failed/Other drops(OIF-null, rate-limit etc)
  RP-tree: Forwarding: 0/0/0/0, Other: 2/2/0
  RP-tree: Forwarding: 3/0/74/0, Other: 3/0/0
  Source: 32.32.32.32/32, Forwarding: 218747/2/74/1, Other: 218747/0/0
  RP-tree: Forwarding: 0/0/0/0, Other: 0/0/0
  Source: 9.4.168.10/32, Forwarding: 31/0/146/0, Other: 3841861/0/3841830
```

Network address translation (NAT)

Explains how network address translation (NAT) mechanisms map private network addresses to public addresses, supporting secure and scalable internet access.

A network address translation is a networking technique that

- allows multiple local IP addresses within a priavte network to be mapped to public IP addresses
- enables devices on private networks to access external (Internet or Cloud) resources, and
- enhances network security by concealing internal addressing schemes from outside networks.

Port address translation (PAT) enables a single IP address to be shared by multiple hosts through the use of IP and port translations.

L3 access on the controller supports only these NAT use cases:

- translating client traffic in the guest network to reach corporate services, such as Cisco ISE, and
- hiding the private IP addresses of clients from outside networks.

These types of NAT are supported:

- Static address translation (static NAT) allows a one-to-one mapping between local and global addresses. The static translation is useful when a host from the inside is accessible from a fixed address from the outside.
- Dynamic address translation (dynamic NAT or PAT) maps between the client subnet and a public global IP address or source port pool.

  This can be achieved using these:

  - Dynamic NAT without VRF.
  - Dynamic NAT with VRF.

Selective NAT support

This topic explains selective NAT supports, which enable only specific NAT features within Cisco IOS XE 17.13.1.

A selective NAT support is a NAT configuration feature that

- enables only a specified subset of NAT options within a software release, and
- ensures compliance with recent Cisco IOS XE 17.13.1 platform capabilities.

Enable static NAT without VRF (CLI)

Use this procedure to configure static Network Address Translation (NAT) without VRF on a Cisco device using commands.

Configure static NAT to enable a device on the internal network to communicate with external networks using a fixed public IP address using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Specify an interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface interface-type number
   ```

3. Set the IP address for an interface.

   Example

   ```
   Device(config-if)# ip address ip-address mask-address
   ```

4. Connect the interface to the outside network.

   Example

   ```
   Device(config-if)# ip nat outside
   ```

5. Exit the interface configuration mode and enter the global configuration mode.

Example

```
Device(config-if)# end
```

6. Specify a different interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface interface-type number
   ```

7. Set the IP address for an interface.

   Example

   ```
   Device(config-if)# ip address ip-address mask-address
   ```

8. Mark the interface as connected to the inside.

   Example

   ```
   Device(config-if)# ip nat inside
   ```

9. Exit the interface configuration mode and enter the global configuration mode. Translate between an inside local address and inside global address.

   Example

   ```
   Device(config-if)# end
   ```

   ```
   Device(config)# ip nat inside source static 10.10.10.100 209.165.200.226
   ```

Enable static NAT with VRF (CLI)

Learn how to configure static NAT with VRF using commands to enable communication between devices in different virtual routing domains.

Establish a static Network Address Translation (NAT) mapping within a specific Virtual Routing and Forwarding (VRF) environment using commands.

Procedure

---

1. Enter the global configuration mode. Specify an interface and enter the interface configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# interface interface-type-number
   ```

2. Activate multiprotocol VRF on an interface.

Example

```
Device(config-if)# vrf forwarding vrf-name
```

3. Enable IP address on an interface.

   Example

   ```
   Device(config-if)# ip address ip-address mask-address
   ```

4. Mark the interface as connected to the outside.

   Example

   ```
   Device(config-if)# ip nat outside
   ```

5. Return to privileged EXEC mode.

   Example

   ```
   Device(config-if)# end
   ```

6. Specify an interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface interface-type-number
   ```

7. Activate multiprotocol VRF on an interface.

   Example

   ```
   Device(config-if)# vrf forwarding vrf-name
   ```

8. Enable IP address on an interface. Mark the interface as connected to the inside.

   Example

   ```
   Device(config-if)# ip address ip-address mask-address
   ```

   ```
   Device(config-if)# ip nat inside
   ```

9. Return to the privileged EXEC mode. Translate between an inside local address and inside global address.

   Example

   ```
   Device(config-if)# end
   ```

   ```
   Device(config)# ip nat inside source static local-ip global-ip vrf vrf_name
   match-in-vrf
   ```

> **Note**
>
> The **match-in-vrf** keyword is optional and required when the same VRF is configured in the inside and outside NAT interface. For more information about match-in-vrf, see
>
> https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipaddr_nat/configuration/xe-16/nat-xe-16-book/iadnat-match-vrf.html

Enable dynamic NAT without VRF (CLI)

Learn how to enable dynamic NAT without VRF using commands, allowing devices on an internal network to share a single public IP address for outbound connections.

Configure a Cisco device to provide dynamic network address translation (NAT) for internal devices without using VRF using commands.

Procedure

1. Enter the global configuration mode. Specify an interface and enter the interface configuration mode.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# interface interface-type number
   ```

2. Set the IP address for an interface.

   Example

   ```
   Device(config-if)# ip address ip address mask-address
   ```

3. Mark the interface as connected to the outside.

   Example

   ```
   Device(config-if)# ip nat outside
   ```

4. Specify a different interface and enter the interface configuration mode.

   Example

   ```
   Device(config)# interface interface-type number
   ```

5. Set the IP address for an interface.

Example

```
Device(config-if)# ip address ip address mask-address
```

6. Mark the interface as connected to the inside.

Example

```
Device(config-if)# ip nat inside
```

7. Define a pool of network addresses for NAT.

Example

```
Device(config)# ip nat pool name start-ip end-ip {netmask netmask |
prefix-length prefix-length}
```

8. Define a standard access list for the addresses to be translated.

Example

```
Device(config)# access-list access-list-number permit ip source-address
source-wildcard-bits host destination-address
```

> **Note**
>
> The **host** keyword is optional for access-list configuration. It depends on the type of ACL you want to configure.

9. Establish dynamic source translation with overloading using the defined access list. Return to the privileged EXEC mode.

Example

```
Device(config)# ip nat inside source list access-list-number pool name overload
```

```
Device(config)# exit
```

Enable dynamic NAT with VRF (CLI)

Use this procedure to enable and configure dynamic NAT for a specific VRF on your device using commands.

Enable dynamic Network Address Translation (NAT) on interfaces associated with a specific Virtual Routing and Forwarding (VRF) instance using commands.

Procedure

---

1. Enter the global configuration mode. Specify an interface and enter the interface configuration mode.

Example

```
Device# configure terminal
```

```
Device(config)# interface interface-type-number
```

2. Activate multiprotocol VRF on an interface. Enable IP address on an interface.

   Example

   ```
   Device(config-if)# vrf forwarding vrf-name
   ```

   ```
   Device(config-if)# ip address ip address mask-address
   ```

3. Mark the interface as connected to the outside. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-if)# ip nat outside
   ```

   ```
   Device(config-if)# end
   ```

4. Specify an interface and enter the interface configuration mode. Activate multiprotocol VRF on an interface.

   Example

   ```
   Device(config)# interface interface-type-number
   ```

   ```
   Device(config-if)# vrf forwarding vrf-name
   ```

5. Enable IP address on an interface. Mark the interface as connected to the inside.

   Example

   ```
   Device(config-if)# ip address ip address mask-address
   ```

   ```
   Device(config-if)# ip nat inside
   ```

6. Return to privileged EXEC mode. Define a standard IPv4 access list using a name.

   Example

   ```
   Device(config-if)# end
   ```

   ```
   Device(config)# ip access-list standard name
   ```

   The *name* can be a number from one to 99.

7. Specify the forwarded packet. Exit interface configuration mode and return to the global configuration mode.

Example

```
Device(config-if)# sequence-number permit host-network wildcard-address
```

```
Device(config-if)# exit
```

> **Note**
>
> *sequence-number* refers to the number where the rule should be in the list. Here, lower the sequence number higher the priority for the rule.

8. Define a pool of network addresses for NAT. Establish dynamic source translation with overloading using the defined access list.

Example

```
Device(config)# ip nat pool name start-ip end-ip {netmask netmask |
prefix-length prefix-length}
```

```
Device(config)# ip nat inside source list access-list-number pool name vrf
vrf-name match-in-vrf overload
```

> **Note**
>
> The **match-in-vrf** keyword is optional and required when the same VRF is configured in the inside and outside NAT interface. For more information about match-in-vrf, see
>
> https://www.cisco.com/c/en/us/td/docs/ios-xml/ios/ipaddr_nat/configuration/xe-16/nat-xe-16-book/iadnat-match-vrf.html

9. Return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Enable timeout for NAT (CLI)

Learn how to set protocol-specific NAT session timeouts using commands.

Adjust the timeout values for NAT translations to optimize device performance using commands.

Procedure

---

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Specify timeouts for NAT translations.

Example

```
Device(config)# ip nat translation [icmp-timeout | tcp-timeout | timeout |
udp-timeout] number-of-seconds
```

These timeout options are supported:

- **icmp-timeout**: ICMP packets timeout.
- **tcp-timeout**: TCP packets timeout.
- **timeout**: Global timeout for all protocol types.
- **udp-timeout**: UDP packets timeout.

3. Return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Verify static NAT details

This section lists the commands and typical outputs for verifying static NAT details, both with and without VRF, on supported devices.

Verify static NAT details without VRF

To verify the static IP NAT statistics without VRF, use this command:

```
Device# show ip nat statistics
Total active translations: 1 (1 static, 0 dynamic; 0 extended)
Outside interfaces:
Vlan62
Inside interfaces:
Vlan55
Hits: 1474 Misses: 0
Reserved port setting disabled provisioned no
Expired translations: 1
Dynamic mappings:
nat-limit statistics:
max entry: max allowed 0, used 0, missed 0
In-to-out drops: 0 Out-to-in drops: 0
Pool stats drop: 0 Mapping stats drop: 0
Port block alloc fail: 0
IP alias add fail: 0
Limit entry add fail: 0
```

To verify the static NAT without VRF on active chassis, use this command:

```
Device# show platform software nat chassis active F0 translation
Pro Inside global Inside local Outside local Outside global
--- 62.1.1.15 155.1.100.1 --- ---
--- 62.1.1.16 155.1.0.4 --- ---
udp 62.1.1.16:33334 155.1.0.4:33334 62.1.1.11:33333 62.1.1.11:33333
udp 62.1.1.16:30000 155.1.0.4:30000 62.1.1.11:30000 62.1.1.11:30000
Total number of translations: 4
```

Verify static NAT details with VRF

To verify the static IP NAT statistics with VRF, use this command:

```
Device# show ip nat statistics
Total active translations: 1 (1 static, 0 dynamic; 0 extended)
Outside interfaces:
Vlan62
Inside interfaces:
Vlan55
Hits: 1474 Misses: 0
Reserved port setting disabled provisioned no
Expired translations: 1
Dynamic mappings:
nat-limit statistics:
max entry: max allowed 0, used 0, missed 0
In-to-out drops: 0 Out-to-in drops: 0
Pool stats drop: 0 Mapping stats drop: 0
Port block alloc fail: 0
IP alias add fail: 0
Limit entry add fail: 0
```

To verify the static NAT with VRF on active chassis, use this command:

```
Device# show platform software nat chassis active F0 translation
Pro Inside global Inside local Outside local Outside global
--- 62.1.1.15 155.1.100.1 --- ---
--- 62.1.1.16 155.1.0.4 --- ---
udp 62.1.1.16:33334 155.1.0.4:33334 62.1.1.11:33333 62.1.1.11:33333
udp 62.1.1.16:30000 155.1.0.4:30000 62.1.1.11:30000 62.1.1.11:30000
Total number of translations: 4
```

Verify dynamic NAT details

This section lists the commands and example outputs used to verify dynamic NAT details, both with and without a VRF, on Cisco devices.

Verify dynamic NAT details without VRF

To verify the dynamic IP NAT statistics without VRF, use this command:

```
Device# show ip nat statistics
Total active translations: 1 (0 static, 1 dynamic; 1 extended)
Outside interfaces:
  Vlan62
Inside interfaces:
  Vlan155
Hits: 3  Misses: 1
 Reserved port setting disabled provisioned no
Expired translations: 0
```

```
Dynamic mappings:
-- Inside Source
[Id: 2] access-list dest_nat_acl pool test_nat_pool refcount 1
 pool test_nat_pool: id 1, netmask 255.255.255.252
    start 62.1.1.101 end 62.1.1.101
    type generic, total addresses 1, allocated 1 (100%), misses 0
longest chain in pool: test_nat_pool's addr-hash: 0, average len 0,chains 0/256
nat-limit statistics:
 max entry: max allowed 0, used 0, missed 0
In-to-out drops: 0  Out-to-in drops: 0
Pool stats drop: 0  Mapping stats drop: 0
Port block alloc fail: 0
IP alias add fail: 0
Limit entry add fail: 0
```

To verify the dynamic NAT without VRF on active chassis, use this command:

```
Device# show platform software nat chassis active F0 translation
Pro  Inside global         Inside local          Outside local         Outside
 global
udp  62.1.1.101:30000      155.1.100.1:30000     62.1.1.11:30000
62.1.1.11:30000
Total number of translations: 1
```

Verify dynamic NAT details with VRF

To verify the dynamic IP NAT statistics with VRF, use this command:

```
Device# show ip nat statistics
Total active translations: 1 (0 static, 1 dynamic; 1 extended)
Outside interfaces:
  Vlan62
Inside interfaces:
  Vlan155
Hits: 3  Misses: 1
 Reserved port setting disabled provisioned no
Expired translations: 0
Dynamic mappings:
-- Inside Source
[Id: 2] access-list dest_nat_acl pool test_nat_pool refcount 1
 pool test_nat_pool: id 1, netmask 255.255.255.252
    start 62.1.1.101 end 62.1.1.101
    type generic, total addresses 1, allocated 1 (100%), misses 0
longest chain in pool: test_nat_pool's addr-hash: 0, average len 0,chains 0/256
nat-limit statistics:
 max entry: max allowed 0, used 0, missed 0
In-to-out drops: 0  Out-to-in drops: 0
Pool stats drop: 0  Mapping stats drop: 0
Port block alloc fail: 0
IP alias add fail: 0
Limit entry add fail: 0
```

To verify the dynamic NAT with VRF on active chassis, use this command:

```
Device# show platform software nat chassis active F0 translation
Pro  Inside global         Inside local          Outside local         Outside
 global
udp  62.1.1.101:30000      155.1.100.1:30000     62.1.1.11:30000
62.1.1.11:30000
Total number of translations: 1
```

Verify NAT details

This section lists commands to verify Network Address Translation (NAT) datapath pool details and statistics, and provides reference details about the output fields and clearing procedures.

To verify the NAT datapath pool details, use this command:

```
Device# show platform hardware chassis active qfp feature nat datapath pool
pool_id 1 type 1 addroute 0 mask 0xfffffffc allocated 0 misses 0 rotary idx
0x0 ahash sz 4 size 1 max_pat_hash_size 1 next 0x0 hash_index 0x32, hilo ports
 0x0 pool mem 0xde480010 flags 0x1 pool_name: test_nat_pool pat_wl 0 no_ports_wl
 0 num_maps 1 num_overload_maps 1 vrf 0x0 port_used tcp 0 udp 0
Conf block info
start 62.1.1.102 end 62.1.1.102 flags 0x0 next 0x0 prev 0x0
TCP PAT block info
UDP PAT block info
ICMP PAT block info
GRE PAT block info
Alloced addr info
```

To verify the NAT datapath statistics, use this command:

```
Device# show platform hardware chassis active qfp feature nat datapath stats
Counter Value
-------------------------------------------------------------------------
number_of_session 0
udp 0
tcp 0
icmp 0
non_extended 0
statics 0
static_net 0
entry_timeouts 0
hits 0
misses 0
cgn_dest_log_timeouts 0
ipv4_nat_alg_bind_pkts 0
ipv4_nat_alg_sd_not_found 0
ipv4_nat_alg_sd_tail_not_found 0
ipv4_nat_rx_pkt 2043
ipv4_nat_tx_pkt 122169
ipv4_nat_flowdb_hits 0
ipv4_nat_stick_rx_pkts 0
ipv4_nat_stick_i2o_pkts 0
ipv4_nat_stick_o2i_pkts 0
ipv4_nat_stick_forus_hits_pkts 0
ipv4_nat_stick_hit_sb 0
ipv4_nat_stick_ha_divert_pkts 0
ipv4_nat_stick_ha_ar_pkts 0
ipv4_nat_stick_ha_tcp_fin 0
ipv4_nat_stick_ha_failed_pkts 0
ipv4_nat_non_natted_in2out_pkts 122165
ipv4_nat_non_nated_out2in_pkts 0
ipv4_nat_bypass_pkts 0
ipv4_nat_unmarked_pkts 0
ipv4_nat_res_port_in2out_pkts 0
ipv4_nat_res_port_out2in_pkts 0
ipv4_nat_ipc_retry_fail 0
ipv4_nat_cfg_rcvd 2
ipv4_nat_cfg_rsp 2
```

To clear the NAT details, use this commands:

```
clear platform software nat chassis active F0 translation forced
clear ip nat statistics
```

Verify NAT timeout details

This section lists the NAT timeout types, their timeout values in seconds, and whether each type is enabled by default.

To verify the NAT timeout details, use this command:

```
Device# show platform software nat chassis active r0 timeout
Dump NAT timeout config
  Type: generic, Timeout (sec): 86400, Enabled: Yes
  Type: tcp, Timeout (sec): 86400, Enabled: Yes
  Type: tcp-pptp, Timeout (sec): 86400, Enabled: Yes
  Type: udp, Timeout (sec): 60, Enabled: Yes
  Type: tcp-fin-reset, Timeout (sec): 60, Enabled: Yes
  Type: tcp-syn, Timeout (sec): 60, Enabled: Yes
  Type: dns, Timeout (sec): 60, Enabled: Yes
  Type: icmp, Timeout (sec): 60, Enabled: Yes
  Type: skinny, Timeout (sec): 60, Enabled: Yes
  Type: icmp-error, Timeout (sec): 60, Enabled: Yes
  Type: esp, Timeout (sec): 300, Enabled: Yes
  Type: rtmap, Timeout (sec): 3600, Enabled: Yes
```

78 IPv6 Layer 3 Access

Topics:

- IPv6 Layer 3 access

This chapter explains IPv6 Layer 3 Access.

IPv6 Layer 3 access

Explains how IPv6 layer 3 access enables controller-based wireless client subnet termination and advanced IPv6 services on the Cisco Catalyst 9800 Series Wireless Controller.

IPv6 Layer 3 access is a controller-based wireless client forwarding capability that

- terminates wireless client IPv6 subnets on switched virtual interfaces (SVIs) on the Cisco Catalyst 9800 Series Wireless Controller
- advertises wireless client routes to the upstream network through OSPFv3, and
- provides VRF-aware IPv6 services such as DHCPv6 relay, IPv6 multicast routing, and NAT64.

In a Layer 2 wireless architecture, an upstream switch or router terminates the wireless client subnets. With IPv6 Layer 3 access, the controller terminates the client subnets and participates in routing. This design can improve scalability, resiliency, and operational efficiency for IPv6-first and dual-stack networks.

IPv6 Layer 3 access supports the coexistence of Layer 2 and Layer 3 WLANs. You can enable Layer 3 access on the wireless policy profiles that require controller-based subnet termination and leave it disabled on other policy profiles.

The controller supports flow based equal-cost multipath (ECMP) forwarding over four equal-cost paths by default. ECMP distributes flows across multiple best paths that have the same routing metric.

Feature history for IPv6 Layer 3 Access

This section explains the feature history details of the IPv6 Layer 3 Access feature.

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 85: Feature history for IPv6 Layer 3 Access

Feature Name	Release Information	Feature Description
IPv6 Layer 3 Access	Cisco IOS XE 26.2.1	IPv6 Layer 3 Access is a controller-based wireless client forwarding capability that terminates IPv6 client subnets on switched virtual interfaces and advertises client routes to the upstream network through OSPFv3. It provides VRF-aware IPv6 services and improves scalability, resiliency, and operational efficiency for IPv6-first and dual-stack networks.

DHCPv6 relay agents

Explains the function and configuration of DHCPv6 relay agents on wireless controllers, including supported options and related Layer 2 relay operations.

A DHCPv6 relay agent is a network function on the wireless controller that

- encapsulates wireless client DHCPv6 messages into relay-forward messages
- sends the relay-forward messages to a DHCPv6 server through unicast communication, and

- decapsulates the client messages from relay-reply messages and forwards them to wireless clients.

You can configure DHCPv6 server settings on a wireless policy profile or an SVI. You can configure the DHCPv6 VPN option at the wireless policy profile, SVI, or global configuration level.

The configuration scope determines which clients the VPN option applies to. A wireless policy profile configuration applies only to clients associated with that policy profile. An SVI configuration applies to clients on the corresponding VLAN. A global configuration applies to all applicable DHCPv6 clients on the controller.

If the VPN option is configured at more than one scope, the controller applies the most specific configuration. A wireless policy profile configuration takes precedence over an SVI configuration, and an SVI configuration takes precedence over the global configuration.

The controller supports primary and secondary DHCPv6 server addresses at configuration scopes that allow multiple relay destinations. A wireless policy profile supports one DHCPv6 server address.

Supported DHCPv6 relay options

- Interface-ID: The Interface-ID option is enabled by default. No configuration is required.
- Virtual Subnet Selection (VSS): Carries the VRF name of the client interface. This option uses Cisco enterprise ID nine, and suboption three carries the VRF name. The DHCPv6 server can use this information to apply policy for the originating VRF.

The client interface VRF is carried in the VSS option. The server VRF determines how the controller routes relay packets to the DHCPv6 server.

Lightweight DHCPv6 relay agents

A lightweight DHCPv6 relay agent (LDRA) is a Layer 2 relay function that inserts relay-agent information while the controller bridges client traffic. LDRA is the functional equivalent of the DHCPv4 Layer 2 relay agent.

When you enable the VPN option on a wireless policy profile without configuring a DHCPv6 server, the controller applies LDRA processing. The controller automatically adds the mandatory Interface-ID option and adds the VSS option only when you configure it.

How IPv6 Layer 3 client forwarding works

Describes the sequence of events and key actors involved in IPv6 Layer 3 client forwarding through Cisco wireless infrastructure.

These stages describe how IPv6 Layer 3 forwarding works.

Summary

The key components involved in the process are:

- *Wireless client*: Connects to a WLAN that uses a wireless policy profile.
- *Access point*: Connects the wireless client to the controller.
- *Cisco Catalyst 9800 Series Wireless Controller*: Terminates the client SVI and forwards client traffic at Layer 3.
- *Upstream routers*: Exchange routes with the controller through OSPFv3 and forward traffic through the enterprise network.

Workflow

The process involves these stages:

1. The wireless client joins a WLAN whose wireless policy profile has Layer 3 access enabled.
2. The controller terminates the client subnet on the corresponding SVI.
3. OSPFv3 advertises the client subnet to the upstream routers.

4. The controller and the upstream routers select the best routing path. When multiple paths have equal metrics, ECMP distributes flows across the equal-cost paths.
5. The controller forwards client traffic through the selected path.

Result

The controller provides routed IPv6 connectivity for wireless clients and advertises the client subnets to the upstream network.

How DHCPv6 relay agents work

Describes how DHCPv6 relay agents facilitate IPv6 address allocation for wireless clients by relaying messages between clients and DHCPv6 servers.

These stages describe how DHCPv6 relay agents work.

Summary

The key components involved in the process are:

- *Wireless client*: Sends DHCPv6 messages to obtain IPv6 configuration.

  Cisco Catalyst 9800 Series Wireless Controller: Relays and processes DHCPv6 messages.

- *DHCPv6 server*: Allocates IPv6 configuration and returns DHCPv6 replies.

Workflow

The process involves these stages:

1. The wireless client sends a multicast DHCPv6 message.
2. The controller selects the effective relay configuration according to the policy profile, SVI, and global precedence.
3. The controller encapsulates the client message in a relay-forward message and adds the required relay options.
4. The controller converts the client multicast exchange into unicast communication with the DHCPv6 server and uses the server VRF to route the relay packet.
5. The DHCPv6 server returns a relay-reply message.
6. The controller decapsulates the relay-reply message and forwards the server-originated reply to the wireless client.

Result

The wireless client receives IPv6 configuration from an external DHCPv6 server through the controller.

Guidelines for IPv6 Layer 3 forwarding

Ensure your IPv6 Layer 3 forwarding deployment meets all mandatory guidelines for reliable wireless client termination, routing, and DHCP relay functionality.

Ensure that the IPv6 Layer 3 forwarding deployment meets these guidelines:

- Enable Layer 3 access on each wireless policy profile that uses controller-based client subnet termination. Layer 3 access is disabled by default.
- Use Local mode or FlexConnect central switching with central DHCP.
- Use OSPFv3 for dynamic routing and static routes for IPv6 reachability to infrastructure devices.
- Configure an external DHCPv6 server for full DHCPv6 relay operation.
- Apply DHCPv6 relay configuration at the intended scope. A wireless policy profile configuration overrides an SVI configuration, and an SVI configuration overrides the global configuration.
- Use the client interface VRF in the VSS option when the DHCPv6 server requires the originating VRF context.

- Use the server VRF to provide destination routing for relay packets to the DHCPv6 server.

Restrictions for IPv6 Layer 3 forwarding

Lists current restrictions on IPv6 layer 3 forwarding across various wireless deployment models.

These restrictions apply to IPv6 Layer 3 forwarding:

- FlexConnect local switching, MEWLC, and ECA deployments are not supported.
- BGP is not supported for this feature.
- The internal DHCPv6 server is not supported.
- Inter-controller mobility is not supported for Layer 3 access clients.
- A client cannot roam between Layer 2 and Layer 3 WLANs that use different VLANs, interfaces, or VRFs. The controller rejects the roam.
- Mobility anchor and static IP mobility configurations are not supported on a wireless policy profile that has Layer 3 access enabled.

Use cases for IPv6 Layer 3 forwarding

Explains how IPv6 Layer 3 forwarding enables routed client connectivity and supports advanced networking use cases in enterprise wireless environments.

IPv6 Layer 3 forwarding supports these use cases:

- *IPv6-first wireless access*: Provides routed client connectivity in an IPv6-first enterprise network.
- *Dual-stack wireless access*: Uses a single OSPFv3 process for IPv4 and IPv6 address families.
- *VRF-aware segmentation*: Maintains separate routing contexts for client networks and supports VRF-aware DHCPv6 relay.
- *Layer 2 and Layer 3 WLAN coexistence*: Allows selected WLANs to use controller-based Layer 3 termination while other WLANs continue to use Layer 2 termination.
- *Resilient upstream connectivity*: Uses OSPFv3 and flow-based ECMP to advertise client subnets and forward traffic across equal-cost paths.
- *IPv6 multicast services*: Supports PIM sparse mode, PIM source-specific multicast, and MLDv2 for wireless clients.
- *IPv6-to-IPv4 communication*: Supports NAT64 so that IPv6-only wireless clients can access IPv4-only resources.

Enable Layer 3 access on a wireless policy profile

Configure Layer 3 access settings on a wireless policy profile so the controller terminates and routes client traffic.

Enable the controller to terminate and route client traffic for a wireless policy profile.

Layer 3 access is disabled by default. Enable it only on wireless policy profiles that require controller-based client subnet termination.

Before you begin

- Configure the client VLAN and SVI.
- Ensure that the deployment uses Local mode or FlexConnect central switching with central DHCP.

Follow these steps to enable Layer 3 access on a wireless policy profile:

Procedure

1. Enter wireless policy profile configuration mode and enable Layer 3 access.

   Example

   ```
   wireless profile policy policy-profile-name l3-access
   ```

   Use the **no** form of this command to disable Layer 3 access.

2. Verify the Layer 3 access state for the policy profile.

   Example

   ```
   show wireless profile policy detailed policy-profile-name | include L3
   ```

   The command displays the L3 access as enabled.

3. Verify the Layer 3 access state for a connected wireless client.

   Example

   ```
   show wireless client mac-address client-mac-address detail | include L3
   ```

   The command displays the L3 access as enabled for a client.

Layer 3 access is enabled for clients that use the wireless policy profile.

Configure DHCPv6 relay or LDRA

Configure your controller to relay DHCPv6 messages or insert DHCPv6 relay-agent information, using DHCPv6 relay or LDRA at the appropriate scope for wireless clients.

Configure the controller to relay DHCPv6 messages or insert DHCPv6 relay-agent information for wireless clients.

You can configure DHCPv6 relay on a wireless policy profile or an SVI. You can enable the DHCPv6 VPN option at the wireless policy profile, SVI, or global configuration level. Select the configuration scope according to the clients to which the VPN option must apply:

- Wireless policy profile: Applies only to clients associated with the wireless policy profile.
- SVI: Applies to clients on the corresponding VLAN.
- Global configuration: Applies to all applicable DHCPv6 clients on the controller.

If the VPN option is configured at more than one scope, the controller applies the configuration in this order of precedence:

- Wireless policy profile
- SVI
- Global configuration

Use LDRA when the controller bridges client traffic and no DHCPv6 server is configured on the wireless policy profile.

Before you begin

- Obtain the IPv6 address of the external DHCPv6 server. You can configure one DHCPv6 server address on a wireless policy profile.

- Configure the VRF that provides reachability to the DHCPv6 server.
- Ensure that routes to the external DHCPv6 server are available.
- Select the configuration scope required by the deployment.

Follow these steps to configure DHCPv6 relay or LDRA:

Procedure

1. Select one of the following configurations according to the required scope and forwarding behavior.

   Full DHCPv6 relay on a wireless policy profile.

   a) Configure the DHCPv6 server address and server VRF. Enable the VPN option when the DHCPv6 server requires the client VRF context.

      Example

      ```
      wireless profile policy policy-profile-name
          ipv6 dhcp server dhcpv6-server-address vrf server-vrf-name
          ipv6 dhcp relay option vpn
      ```

      You can configure only one DHCPv6 server address on a wireless policy profile.

   LDRA on a wireless policy profile.

   a) Do not configure a DHCPv6 server on a wireless policy profile that uses LDRA. Enable the VPN option to apply LDRA processing.

      Example

      ```
      wireless profile policy policy-profile-name
          ipv6 dhcp relay option vpn
      ```

      The controller automatically inserts the mandatory Interface-ID option. It adds the VSS option only when the VPN option is configured.

   DHCPv6 relay on an SVI.

   a) Configure the relay destination. Include the server VRF, link address, source address, or source interface when required by the deployment.

      Example

      ```
      interface Vlan vlan-id
          ipv6 dhcp relay destination dhcpv6-server-address link-address link-address |
       source-address source-address
          ipv6 dhcp relay destination vrf server-vrf-name dhcpv6-server-address
      link-address link-address | source-address source-address
          ipv6 dhcp relay source-interface source-interface
          ipv6 dhcp relay option vpn
      ```

      Use only the relay destination form and optional parameters required by the deployment.

   Global DHCPv6 relay VPN option.

   a) Enable the VPN option globally when it must apply to all applicable DHCPv6 clients on the controller.

A wireless policy profile or SVI configuration takes precedence over the global configuration.

Example

```
ipv6 dhcp-relay option vpn
```

2. Connect a wireless client and confirm that it receives IPv6 configuration from the external DHCPv6 server.

The controller applies the selected DHCPv6 relay or LDRA behavior at the configured scope.

Configure OSPFv3 for IPv6 Layer 3 access

Configure OSPFv3 to advertise wireless client subnets and learn upstream IPv6 routes for Layer 3 access.

Enable IPv6 routing on wireless client VLANs by configuring OSPFv3 to advertise subnets and learn upstream routes.

OSPFv3 supports both IPv4 and IPv6 address families, including VRF-specific deployments.

Before you begin

- Configure the client VLAN, SVI, IPv6 address, and VRF.
- Confirm the OSPFv3 process ID and area for the deployment.

Follow these steps to configure OSPFv3 for IPv6 Layer 3 access:

Procedure

---

1. Configure the OSPFv3 process and IPv6 unicast address family. Configure a VRF-specific address family when required.

   Configure BFD and nonstop routing (NSR) only when required by the network design.

2. Associate the client SVI with the OSPFv3 process and area for IPv6.

   Example

   ```
   interface Vlan vlan-id
   vrf forwarding vrf-name
   ipv6 address ipv6-prefix prefix-length
   ipv6 enable
   ospfv3 process-id ipv6 area area-id
   ```

3. For a dual-stack deployment, configure the IPv4 address family and associate the SVI with the OSPFv3 process for IPv4.
4. Verify the OSPFv3 neighbors and learned IPv6 routes.

The controller exchanges IPv6 routes with its OSPFv3 neighbors and advertises the configured client subnets.

Configure IPv6 multicast routing for wireless clients

Configure IPv6 multicast routing on Layer 3 wireless clients to support PIM sparse mode, source-specific multicast, and MLDv2.

Enable Layer 3 wireless clients to receive IPv6 multicast traffic through proper routing and group management.

IPv6 multicast routing for wireless clients allows efficient group-based communication, supporting advanced protocols such as PIM and MLD.

Before you begin

- Configure the client VRF and IPv6 SVI.
- Identify the rendezvous point and wireless IPv6 multicast group for the deployment.

Follow these steps to configure IPv6 multicast routing for wireless clients:

Procedure

1. Enable IPv6 unicast routing, multicast routing for the client VRF, and MLD snooping.

   Example

   ```
   ipv6 unicast-routing
   ipv6 multicast-routing vrf vrf-name
   ipv6 mld snooping
   ipv6 mld vrf vrf-name state-limit state-limit
   ```

2. Configure the IPv6 PIM rendezvous point for the client VRF.

   Example

   ```
   ipv6 pim vrf vrf-name rp-address rp-ipv6-address
   ```

3. Enable wireless multicast and configure the AP CAPWAP IPv6 multicast group.

   Example

   ```
   wireless multicast
   wireless multicast ipv6 ipv6-multicast-group
   ```

4. Verify the wireless multicast configuration and IPv6 group membership.

The controller forwards supported IPv6 multicast traffic for Layer 3 wireless clients.

79 Network Mobility Services Protocol

Topics:

- Network mobility services protocol
- Probe RSSI location
- RFID tag support

Network mobility services protocol

Explains the Network Mobility Services Protocol (NMSP) and its role in secure, bi-directional wireless communication between controllers and Cisco Connected Mobile Experiences (CMX) clients.

A Network Mobility Services Protocol (NMSP) is a secure two-way wireless communication protocol that

- enables bi-directional data exchange between Cisco wireless controllers and Cisco Connected Mobile Experiences (CMX)
- supports both publish-subscribe and request-reply communication models over connection-oriented transports such as TLS, and
- allows controllers to provide multiple services including device location, probe RSSI, hyperlocation, and wIPS to multiple CMX clients.

The wireless infrastructure runs the NMSP server, while Cisco Connected Mobile Experiences (Cisco CMX) acts as the NMSP client.

Cisco CMX communicates to the controller over a routed IP network. Typically, Cisco CMX establishes a subscription to receive services data from the controller in the form of periodic updates. The controller acts as a data publisher, broadcasting services data to multiple CMXs. In addition to subscriptions, Cisco CMX can send requests to the controller. The controller sends a response to Cisco CMX.

This is a list of the Network Mobility Services Protocol features:

- NMSP is disabled by default.
- NMSP communicates with Cisco CMX using TCP, and uses TLS for encryption.
- TCP and TLS support the wireless intrusion prevention system (wIPS).
- The system supports bidirectional communication, and Cisco CMX sends messages asynchronously over the established channel.

> **Note**
>
> HTTPS is not supported for data transport between the controller and Cisco CMX.

Radioactive tracing for NMSP

This feature collects and provides all CMX-related events.

A radioactive trace event is a CMX service feature that

- enables the collection of all CMX-related events from network controllers
- configures secure connections through SNMP and CLI for real-time event tracing, and
- provides comprehensive troubleshooting by gathering controller logs associated with the CMX IP via RA tracing.

This feature also configures the CMX hash key on the controller, and requests the controller to open an NMSP connection.

Enable NMSP on premises services (CLI)

Enable NMSP on premises services using commands.

Enable Network Mobility Services Protocol (NMSP) on your network controller to support communication with on-premises services.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable NMSP on premises services.

   Example

   ```
   Device(config)# nmsp enable
   ```

   Note

   By default, the NMSP is enabled on the controller.

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, press Ctrl-Z to exit global configuration mode.

Modify the NMSP notification interval for clients, RFID tags, and rogues (CLI)

Modify the NMSP notification interval for clients, RFID tags, and rogues.

NMSP manages communication between the Cisco Connected Mobile Experience (Cisco CMX) and the controller for incoming and outgoing traffic. If your application requires more frequent location updates, you can set the NMSP notification interval to a value between one and 180 seconds for clients, active RFID tags, rogue access points, and clients.

Note

The TCP port (16113) used for communication between the controller and Cisco CMX must be open on any firewall separating the two systems to enable NMSP operation.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Set the NMSP notification interval value for clients, RFID tags, rogue clients, and APs.

Example

```
Device(config)# nmsp notification interval {rssi {clients | rfid | rogues {ap
 | client} | spectrum | interferers} interval 50}
```

interval-NMSP notification interval value, in seconds for RSSI measurement. The valid range is from one to 180.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, you can also press ***Ctrl-Z*** to exit global configuration mode.

Modify the NMSP notification threshold for clients, RFID tags, and rogues (CLI)

Modify the NMSP notification threshold for clients, RFID tags, and rogues using commands.

Change the threshold for NMSP notifications based on RSSI for clients, RFID tags, and rogue devices.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the NMSP notification threshold for clients, RFID tags, rogue clients, and APs.

Example

```
Device(config)# location notify-threshold {clients | rogues ap | tags}
threshold 5
```

The *threshold*- RSSI threshold value is in dB. The valid range is from zero to 10, with a default value of zero..

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, press ***Ctrl-Z*** to exit global configuration mode.

Configure NMSP strong cipher (CLI)

Configure NMSP Strong Cipher using commands.

Enable strong cipher suites for NMSP server to enhance security for device communication.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable strong ciphers for NMSP server.

   Example

   ```
   Device(config)# nmsp strong-cipher
   ```

   Strong ciphers for NMSP server contains, "ECDHE-RSA-AES128-GCM-SHA256:, ECDHE-ECDSA-AES128-GCM-SHA256:, AES256-SHA256:AES256-SHA:, and AES128-SHA256:AES128-SHA".

   Normal cipher suite contains, "ECDHE-RSA-AES128-GCM-SHA256:, ECDHE-ECDSA-AES128-GCM-SHA256:, and AES128-SHA".

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

   Alternatively, press ***Ctrl-Z*** to exit global configuration mode.

Verify NMSP settings

Verify NMSP settings using the commands controller .

To view the NMSP capabilities of the controller, use the command:

```
Device# show nmsp capability
Service            Subservice
----------------------------
RSSI               Rogue, Tags, Mobile Station,
Spectrum           Aggregate Interferer, Air Quality, Interferer,
Info               Rogue, Mobile Station,
Statistics         Rogue, Tags, Mobile Station,
AP Monitor         Subscription
On Demand Services Device Info
AP Info            Subscription
```

To view the NMSP notification intervals, use the command:

```
Device# show nmsp notification interval
NMSP Notification Intervals
```

```
--------------------------

RSSI Interval:
Client              : 2 sec
RFID                : 50 sec
Rogue AP            : 2 sec
Rogue Client        : 2 sec
Spectrum            : 2 sec
```

To view the connection-specific statistics counters for all CMX connections, use the command:

```
Device# show nmsp statistics connection
NMSP Connection Counters
----------------------
 CMX IP Address: 10.22.244.31, Status: Active
 State:
 Connections : 1
 Disconnections : 0

 21  Statistics Response                      2
 22  Statistics Notification                305
 31  Service Subscribe Response               1
 67  AP Info Notification                   304
```

To view the common statistic counter of the controller 's NMSP service, use the command:

```
Device# show nmsp statistics summary
NMSP Global Counters
--------------------
Number of restarts                :

SSL Statistics
--------------------
Total amount of verifications      : 6
Verification failures              : 6
Verification success               : 0
Amount of connections created      : 8
Amount of connections closed       : 7
Total amount of accept attempts    : 8
Failures in accept                 : 0
Amount of successful accepts       : 8
```

```
Amount of failed registrations     : 0

AAA Statistics
--------------------
Total amount of AAA requests       : 7
Failed to send requests            : 0
Requests sent to AAA               : 7
Responses from AAA                 : 7
Responses from AAA to validate     : 7
Responses validate error           : 6
Responses validate success         : 1
```

To view the overall NMSP connections, use the command:

```
Device# show nmsp status
NMSP Status
-----------

CMX IP Address   Active    Tx Echo Resp  Rx Echo Req   Tx Data     Rx Data
  Transport
-------------------------------------------------------------------------------------
127.0.0.1        Active    6             6             1           2
  TLS
```

To view all mobility services subscribed by all CMXs, use the command:

```
Device# show nmsp subscription detail
CMX IP address 127.0.0.1:
Service            Subservice
-----------------------------
RSSI               Rogue, Tags, Mobile Station,
Spectrum
Info               Rogue, Mobile Station,
Statistics         Tags, Mobile Station,
AP Info            Subscription
```

To view all mobility services subscribed by a specific CMX, use the command:

```
Device# show nmsp subscription detail
CMX IP address 127.0.0.1:
Service            Subservice
-----------------------------
RSSI               Rogue, Tags, Mobile Station,
Spectrum
Info               Rogue, Mobile Station,
Statistics         Tags, Mobile Station,
AP Info            Subscription

Device# show nmsp subscription summary
Service            Subservice
-----------------------------
RSSI               Rogue, Tags, Mobile Station,
Spectrum
Info               Rogue, Mobile Station,
Statistics         Tags, Mobile Station,
AP Info            Subscription
```

Examples: NMSP settings configuration

NMSP settings configuration examples.

This example shows how to configure the NMSP notification interval for RFID tags:

```
Device# configure terminal
Device(config)# nmsp notification interval rssi rfid 50
Device(config)# end
Device# show nmsp notification interval
```

This example shows how to configure the NMSP notification interval for clients:

```
Device# configure terminal
Device(config)# nmsp notification interval rssi clients 180
Device(config)# end
Device# show nmsp notification interval
```

NMSP by AP groups with subscription list from CMX

Cisco CMX group support allows sending only the required (NMSP) data to Cisco CMX.

An NMSP subscription by AP groups is a network data management feature that

- enables Cisco CMX to subscribe only to specific Network Mobility Services Protocol (NMSP) data from designated AP groups based on the active services in the wireless controller
- helps distribute and balance network data load among multiple CMX servers, and
- restricts NMSP data transmission to those services enabled on the wireless controller.

Cisco CMX group support lets you send the required Network Mobility Services Protocol (NMSP) data to Cisco CMX, whether it is deployed on-premises or in the cloud.

You can create a CMX AP group on the Cisco CMX server, assign a unique name, and group APs under it.

> **Note**
>
> The CMX AP group lists Cisco APs managed by Cisco CMX for location services. This group is different from the AP groups on the wireless controller.

This feature supports these services:

- Client
- Probe client filtering
- Hyperlocation
- BLE Services

> **Note**
>
> NMSP subscription is available only for services enabled on the wireless controller.

Verify NMSP by AP groups with subscription list from CMX

Verify NMSP by AP Groups with subscription list from CMX.

To verify mobility services group subscription summary of all CMX connections, use the command:

```
Device# show nmsp subscription group summary

CMX IP address: 127.0.0.1
Groups subscribed by this CMX server:
Group name: Group1
```

To view the services that are subscribed for an AP group by a CMX connection, use the command:

```
Device# show nmsp subscription group details services cmx-IP-addrress

CMX IP address: 127.0.0.1
CMX Group name: Group1
CMX Group filtered services:
Service            Subservice
----------------------------
RSSI               Mobile Station,
Spectrum
Info
Statistics
```

To view the AP MAC list that is subscribed for an AP group by a CMX connection, use the command:

```
Device# show nmsp subscription group detail ap-list group-name cmx-IP-addrress

CMX IP address: 127.0.0.1
CMX Group name: Group1
CMX Group AP MACs:
: 0000.0000.7002  0000.0000.6602  0099.0000.0002  0000.00bb.0002
  0000.0000.5502  0000.0000.5002  0033.0000.0002  00d0.0000.0002

```

Probe RSSI location

Explains how Probe RSSI locations enable wireless controllers and Cisco CMX to use signal strength data from client probes for advanced location and network management functions.

A probe RSSI location is a wireless networking feature that

- allows wireless controllers and Cisco CMX to collect and use the received signal strength indication (RSSI) from client probe requests associated with the identified Service Set Identifiers (SSIDs)
- enables functions such as load balancing, coverage hole detection, and location updates, and
- supports the precise tracking of wireless clients as they move within the network.

After connecting to an AP, the client scans in the background and keeps a list of strong APs. If it loses connection, the client uses this list to reconnect. The APs in the WLAN gather probe requests, RSSI data, and MAC addresses of wireless clients, then forward this information to the wireless controller s. Cisco CMX receives this data from the controller and calculates the client's updated location.

Configure probe RSSI (CLI)

Configure probe RSSI using commands.

Improve client location accuracy by configuring probe RSSI handling and related settings using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable filtering of unacknowledged probe requests from AP to improve the location accuracy.

   Example

   ```
   Device(config)# wireless probe filter
   ```

   Filtering is enabled by default.

   Use the **no** form of the command to disable the feature. This forwards both acknowledged and unacknowledged probe requests to the controller.

3. Configure the number of probe request reported to the wireless controller from the AP for the same client on a given interval.

   Example

   ```
   Device(config)# wireless probe limit limit-value 10 interval 100
   ```

   Use the **no** form of the command to revert to the default limit, which is two probes at an interval of 500 ms.

4. Enable the reporting of probes from clients having locally administered MAC address.

   Example

   ```
   Device(config)# wireless probe locally-administered-mac
   ```

5. Set the probe RSSI measurement updates to a more accurate algorithm but with more CPU overhead.

   Example

   ```
   Device(config)# location algorithm rssi-average
   ```

6. Optional: Set the probe RSSI measurement updates to a faster algorithm with smaller CPU overhead, but less accuracy.

   Example

   ```
   Device(config)# location algorithm simple
   ```

   Use the **no** form of the command to revert the algorithm type to the default one, that is *rssi-average*.

7. Configure the timeout for RSSI values.

Example

```
Device(config)# location expiry client interval 300
```

The **no** form of the command sets it to a default value of 15.

8. Configure the notification threshold for clients.

Example

```
Device(config)# location notify-threshold client threshold-db 5
```

The **no** form of the command sets it to a default value of zero.

9. Configure half life when averaging two RSSI readings.

Example

```
Device(config)# location rssi-half-life client time-in-seconds 20
```

To disable this option, set the value to zero.

What to do next

Use the **show wireless client probing** command to view each probing client (associated and probing only) by batch of 10 MAC addresses.

RFID tag support

Explains the role and characteristics of RFID tags in wireless asset tracking.

An RFID tag is a small wireless battery-powered tracking device that

- broadcasts its own signal for real-time location tracking, and
- operates using special 802.11 packets processed by APs, wireless controllers, and Cisco CMX.

The controller enables you to configure radio frequency identification (RFID) tag tracking. Only active RFIDs are supported. A combination of active RFID tags and wireless controller allows you to track the current location of equipment. Use *Active* tags to track high-value assets in *closed-loop* systems. These tags remain within the control premises of the owner.

General guidelines

- You can verify the RFID tags on the controller .
- The controller supports high availability for RFID tags.

Configure RFID tag support (CLI)

Configure RFID tag support using commands.

Enable and configure RFID tag tracking features for WLANs managed by the device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable RFID tag tracking.

   Example

   ```
   Device(config)# wireless rfid
   ```

   The default value is enabled.

   Use the **no** form of this command to disable RFID tag tracking.

3. Configure the RFID tag data timeout value to cleanup the table.

   Example

   ```
   Device(config)# wireless rfid timeout timeout-value 90
   ```

   The timeout value is the amount of time that the controller maintains tags before expiring them. For example, if a tag is configured to beacon every 30 seconds, we recommend that you set the timeout value to 90 seconds (approximately three times the beacon value). The default value is 1200 seconds.

Verify RFID tag support

Verify RFID tag support details.

To view the summary of RFID tags that are clients, use the command:

```
Device# show wireless rfid client
```

To view the detailed information for an RFID tag, use the command:

```
Device# show wireless rfid detail rfid-mac-address

80 Application Visibility and Control

Topics:

- Application visibility and control
- Default DSCP on AVC
- AVC-based selective reanchoring

Application visibility and control

Explains how application visibility and control enables real-time identification, monitoring, and management of network applications using deep packet inspection and Flexible NetFlow integration.

Application visibility and control is a wireless network feature set that

- enables real-time identification and monitoring of applications using deep packet inspection
- allows creation of policy rules to manage application bandwidth and usage, and
- integrates with Flexible NetFlow (FNF) to report traffic statistics per application or protocol.

Application visibility and control (AVC) is a subset of the Flexible NetFlow (FNF) package. AVC provides traffic information. The AVC feature uses a distributed approach that benefits from NBAR running on the AP or controller. The goal is to run deep packet inspection (DPI) and report the results using FNF messages.

The NBAR2 engine analyzes and recognizes traffic flows. Each specific flow is marked with the detected protocol or application. You can use this per-flow information for application visibility through FNF. After application visibility is established, you can define control rules with policing mechanisms for a client.

Guidelines for application visibility and control

Guidelines for application visibility and control

- Using AVC rules, bandwidth for a particular application can be limited for all clients joined on the WLAN. These bandwidth contracts coexist with per-client downstream rate limiting. The per-client limits take precedence over the per-application rate limits.
- The FNF feature is supported in wireless deployments. It relies on NetFlow enablement on the controller for all modes: FlexConnect, local and Fabric.
- In local mode, NBAR runs on the controller hardware. Client traffic flows through the data plane of the controller using the AP CAPWAP tunnels.
- In FlexConnect or Fabric mode, NBAR runs on the AP. Only statistics are sent to the controller . In these two modes, APs regularly send FNFv9 reports to the controller . The FNF feature uses these reports to provide application statistics reported by AVC.
- In Fabric mode, FNF cache is not populated. The system relays FNFv9 reports as they arrive. As a result, some flow monitor configuration parameters, such as cache timeout, are not used.

The behavior of the AVC solution changes based on the wireless deployment mode. The next sections describe the commonalities and differences in all scenarios.

Local Mode

- NBAR is enabled on the controller .
- AVC does not push the FNF configuration to the APs.
- Roaming events are ignored.

  However, AVC supports Layer 3 roaming in local mode because traffic flows through the anchor controller, where NBAR first processed the client's traffic when the client joined.
- IOSd needs to trigger NBAR attach.
- The solution supports flow monitor cache and NetFlow exporter.

FlexConnect Mode

- NBAR is enabled on an AP.
- AVC pushes the FNF configuration to the APs.
- Context transfer for roaming is supported in AVC-FNF.
- Flow monitor cache is supported.
- NetFlow exporter is supported.

Fabric Mode

- NBAR is enabled on an AP.
- AVC pushes the FNF configuration to the APs.
- Context transfer for roaming is supported in AVC-FNF.
- Flow monitor cache is not supported.
- NetFlow exporter is supported. For the C9800 on Catalyst switches for SDA, FNF cache is not available on the device.

Prerequisites for application visibility and control

Prerequisites for application visibility and control

- The APs should be AVC capable.

  However, this requirement does not apply in Local mode.
- Configure the application visibility feature with FNF to enable AVC control (QoS).

Restrictions for application visibility and control

Restrictions for application visibility and control.

- IPv6 packet classification, including ICMPv6 traffic, is not supported in FlexConnect mode or Fabric mode. It is supported in Local mode.
- Layer 2 roaming is not supported across controller .
- Multicast traffic is not supported.
- AVC is supported only on the following APs:
  - Cisco Catalyst 9100 Series Access Points
  - Cisco Aironet 1800 Series Access Points
  - Cisco Aironet 2700 Series Access Point
  - Cisco Aironet 2800 Series Access Point
  - Cisco Aironet 3700 Series Access Points
  - Cisco Aironet 3800 Series Access Points
  - Cisco Aironet 4800 Series Access Points
  - Cisco Industrial Wireless 3702 Access Point
- AVC is not supported on Cisco Aironet 702W, 702I (128 M memory), and 1530 Series APs.

- Only applications recognized by App Visibility can be used for applying QoS control.
- Data link is not supported for NetFlow fields in AVC.
- You cannot map the same WLAN profile to both the AVC-not-enabled policy profile and the AVC-enabled policy profile.
- AVC is not supported on the management port (Gig 0/0).
- NBAR-based QoS policy configuration is allowed only on wired physical ports. Policy configuration is not supported on virtual interfaces. For example, VLAN, port channel and other logical interfaces.
- NBAR cannot classify traffic accurately when SaaS applications use end-to-end encryption, QUIC, or DoH because encryption affects classification. In these cases, encrypted traffic including DoH and QUIC without SNI prevents NBAR from sending the correct Protocol ID, which causes traffic classification issues.

When AVC is enabled, the profile supports a maximum of 23 rules, including the default DSCP rule. If the number of rules exceeds 23, the AVC policy will not be sent to the AP.

Configure AVC

To configure AVC, follow these steps:

Enable monitoring and policy enforcement for application usage on the wireless network.

Procedure

1. Create a flow monitor using the **record wireless avc basic** command.
2. Create a wireless policy profile.
3. Apply the flow monitor to the wireless policy profile.
4. Create a wireless policy tag.
5. Map the WLAN to the policy profile.
6. Attach the policy tag to the APs.

Create a flow monitor (CLI)

Create a flow monitor using commands.

The NetFlow configuration requires a flow record, a flow monitor, and a flow exporter. Make this configuration your first step in the overall AVC configuration.

Note

In FlexConnect mode and Local mode, the default values for **cache timeout active** and **cache timeout inactive** commands do not provide optimal AVC performance. Set both values to 60 in the flow monitor.

For Fabric mode, the cache timeout configuration does not apply.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Create a flow monitor.

Example

```
Device(config)# flow monitor monitor-name fm_avc
```

3. Specify the basic IPv4 or IPv6 wireless AVC flow template.

Example

```
Device(config-flow-monitor)# record wireless avc {ipv4 | ipv6} basic
```

> **Note**
>
> If you want to have both Application Performance Monitoring (APM) and AVC-FNF in the device simultaneously, use the **record wireless avc {ipv4 | ipv6} assurance** command, which is a superset of the fields contained in **record wireless avc {ipv4 | ipv6} basic** command. If the containing flow monitor is configured with the local exporter using **destination wlc local**command, AVC-FNF will populate the statistics exactly as that of the **record wireless avc {ipv4 | ipv6} basic** configuration. As a result, both APM and AVC-FNF can be configured simultaneously with two flow monitors per direction, per IP version, in local (central switching) mode.

> **Note**
>
> The **record wireless avc basic** command is same as **record wireless avc ipv4 basic** command. However, **record wireless avc ipv4 basic** command is not supported in FlexConnect or Fabric modes. In such scenarios, use the **record wireless avc basic** command.

4. Set the active flow timeout in seconds.

Example

```
Device(config-flow-monitor)# cache timeout active value 60
```

5. Set the inactive flow timeout in seconds.

Example

```
Device(config-flow-monitor)# cache timeout inactive value 60
```

Configure a flow monitor (GUI)

Configure a flow monitor using GUI.

Set up a flow monitor and export data to a collector using a pre-configured flow exporter.

Before you begin
Ensure you have already created a flow exporter.

Procedure

1. Choose **Configuration** > **Services** > **Application Visibility** and go to the **Flow Monitor** tab.
2. In the **Monitor** area, click **Add** to add a flow monitor.
3. In the **Flow Monitor** window, add a flow monitor and a description.
4. Select the Flow exporter from the drop-down list to export data from the flow monitor to the collector.

   Note

   To export wireless NetFlow data, use these templates:

   - ETA (Encrypted Traffic Analysis)
   - wireless avc basic
   - wireless avc basic IPv6

5. Click **Apply to Device** to save the configuration.

Create a flow record (CLI)

Create a flow record using commands.

The default flow record cannot be edited or deleted. If you require a new flow record, create one and map it to the flow monitor from the CLI.

Procedure

1. Create a flow record.

   Example

```
Device(config)# flow record flow_record_name record1
```

> **Note**
>
> When a custom flow record is configured in FlexConnect and Fabric modes, the optional fields (fields that are not present in record wireless avc basic) are ignored.

2. Optional: Describe the flow record as a maximum 63-character string.

   Example

   ```
   Device(config-flow-record)# description IPv4flow
   ```

3. Specify a match to the IPv4 protocol and specify a match to the IPv4 source address-based field.

   Example

   ```
   Device(config-flow-record)# match ipv4 protocol
   ```

   ```
   Device(config-flow-record)# match ipv4 source address
   ```

4. Specify a match to the IPv4 destination address-based field and specify a match to the transport layer's source port field.

   Example

   ```
   Device(config-flow-record)# match ipv4 destination address
   ```

   ```
   Device(config-flow-record)# match transport source-port
   ```

5. Specify a match to the transport layer's destination port field and specify a match to the direction the flow was monitored in.

   Example

   ```
   Device(config-flow-record)# match transport destination-port
   ```

   ```
   Device(config-flow-record)# match flow direction
   ```

6. Specify a match to the application name.

   Example

   ```
   Device(config-flow-record)# match application name
   ```

> **Note**
>
> This action is mandatory for AVC support because this allows the flow to be matched against the application.

7. Specify a match to the SSID name identifying the wireless network and collect the counter field's total bytes.

   Example

   ```
   Device(config-flow-record)# match wireless ssid
   ```

   ```
   Device(config-flow-record)# collect counter bytes long
   ```

8. Collect the counter field's total packets and collect the BSSID with the MAC addresses of the APs that the wireless client is associated with.

   Example

   ```
   Device(config-flow-record)# collect counter packets long
   ```

   ```
   Device(config-flow-record)# collect wireless ap mac address
   ```

9. Collect the MAC address of the client on the wireless network.

   Example

   ```
   Device(config-flow-record)# collect wireless client mac address
   ```

Create a flow exporter (CLI)

Create a flow exporter using commands.

Define export parameters for a flow exporter so AVC statistics are visible on the controller embedded wireless controller. This is an optional procedure for configuring flow exporter parameters.

Note

For the AVC statistics to be visible at the controller, you should configure a local flow exporter using these commands:

- **flow exporter** *my_local*
- **destination local wlc**

Also, your flow monitor must use this local exporter for the statistics to be visible at the controller .

Procedure

1. Create a flow monitor.

   Example

   ```
   Device(config)# flow exporter flow-export-name export-test
   ```

2. Describe the flow record as a maximum 63-character string.

   Example

   ```
   Device(config-flow-exporter)# description IPv4flow
   ```

3. **Example**

   ```
   Device(config-flow-exporter)# destination {hostname/ipv4address |
   hostname/ipv6address | local wlc}
   ```

4. Specify the local controller to which the exporter sends data.

   Example

   ```
   Device(config-flow-exporter)# destination {hostname/ipv4address |
   hostname/ipv6address | local wlc}
   ```

5. Optional: Configure the destination UDP port to reach the external collector.

   Example

   ```
   Device(config-flow-exporter)# transport udp port-value 1024
   ```

   The default value is 9995.

> **Note**
>
> This step is required only for external collectors; not required for local controller collector.

6. Optional: Specify the application table timeout option, in seconds.

   Example

   ```
   Device(config-flow-exporter)# option application-table timeout 500
   ```

   The valid range is from one to 86400.

7. Return to privileged EXEC mode.

   Example

   ```
   Device(config-flow-exporter)# end
   ```

8. Optional: Verify your configuration.

   Example

   ```
   Device# show flow exporter
   ```

Configure a policy tag (CLI)

Configure a policy tag using commands.

Establish a policy tag to control wireless device and SSID behavior.

Policy tags allow you to associate specific policy profiles with APs, enabling customized wireless network behavior.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure policy tag and enter policy tag configuration mode.

   Example

   ```
   Device(config-policy-tag)# wireless tag policy policy-tag-name
   rr-xyz-policy-tag
   ```

3. Save the configuration and exit configuration mode and return to privileged EXEC mode. **end**

Example

```
Device(config-policy-tag)# end
```

Attach a policy profile to a WLAN interface (GUI)

Attach a policy profile to a WLAN interface using GUI.

Link the appropriate policy configuration to a WLAN interface for centralized control. Use the GUI to ensure new or modified policy profiles are correctly associated with WLANs before deployment.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Tags**.
2. On the **Manage Tags** page, click the **Policy** tab.
3. Click **Add** to open the **Add Policy Tag** window.
4. Enter a name and description for the policy tag.
5. Click **Add** to map WLAN and policy.
6. Select the WLAN profile to map with the appropriate policy profile, and click the tick icon.
7. Click **Save & Apply to Device**.

Attach a policy profile to a WLAN interface (CLI)

Attach a policy profile to a WLAN interface using commands.

Assign a policy profile to a WLAN interface to control traffic and services for that WLAN.

Before you begin

Procedure

1. Create a policy tag.

   Example

   ```
   Device(config)# wireless tag policy avc-tag
   ```

2. Attach a policy profile to a WLAN profile.

   Example

   ```
   Device(config-policy-tag)# wlan wlan_avc policy avc_pol
   ```

What to do next

- Do not attach different AVC policy profiles to the same WLAN across different policy tags.

This is an example of incorrect configuration:

```
wireless profile policy avc_pol1
ipv4 flow monitor fm-avc1 input
ipv4 flow monitor fm-avc1 outputno shutdown
wireless profile policy avc_pol2
ipv4 flow monitor fm-avc2 input
ipv4 flow monitor fm-avc2 output
no shutdown
wireless tag policy avc-tag1
wlan wlan1 policy avc_pol1
wireless tag policy avc-tag2
wlan wlan1 policy avc_pol2
```

This example violates the restriction stated earlier, that is, the WLAN *wlan1* is mapped to 2 policy profiles, *avc_pol1* and *avc_pol2*. This configuration is incorrect because the WLAN *wlan1* must be mapped to either *avc_pol1* or *avc_pol2* throughout the configuration..

- Conflicting policy profiles on the same WLAN are not supported. For example, policy profile (with and without AVC) applied to the same WLAN in different policy tags.

  This is an example of an incorrect configuration:

```
wireless profile policy avc_pol1
no shutdown
wireless profile policy avc_pol2
ipv4 flow monitor fm-avc2 input
ipv4 flow monitor fm-avc2 output
no shutdown
wireless tag policy avc-tag1
wlan wlan1 policy avc_pol1
wireless tag policy avc-tag2
wlan wlan1 policy avc_pol2
```

  In this example, a policy profile with and without AVC is applied to the same WLAN in different tags.

- Run the **no shutdown** command on the WLAN after completing the configuration.
- If the WLAN is already in **no shutdown** mode, run the **shutdown** command, then run the **no shutdown** command.

Attach a policy profile to an AP (CLI)

Attach a policy profile to an AP using commands.

Assign a specific policy profile to an AP through commands.

Procedure

1. Enter AP configuration mode.

   Example

```
Device(config)# ap ap-ether-mac 34a8.2ec7.4cf0
```

2. Specify the policy tag that is to be attached to the AP.

Example

```
Device(config)# policy-tag avc-tag
```

Verify the AVC configuration (CLI)

Verify the AVC configuration using commands.

Review and validate the Application Visibility and Control (AVC) configuration on a device.

Procedure

1. Display information about the top applications and the users who use them.

   Example

   ```
   Device# show avc wlan wlan_avc top 2 applications {aggregate | downstream | upstream}
   ```

   Note

   To collect accurate statistics, ensure that wireless clients are connected to the WLAN and transmitting data. After 90 seconds, run the command.

2. Display information about the top applications for the client.

   Example

   ```
   Device# show avc client 9.3.4 top 3 applications {aggregate | downstream | upstream}
   ```

   Note

   Ensure that wireless clients are connected to the WLAN and transmitting data. Wait 90 seconds for statistics to become available, then run the command.

3. Display information about the top applications and the users who uses them.

   Example

   ```
   Device# show avc wlan wlan_avc application app top 4 aggregate
   ```

4. Display a summary of all the APs attached to the controller .

Example

```
Device# show ap summary
```

5. Display a summary of all the APs with policy tags.

Example

```
Device# show ap tag summary
```

Default DSCP on AVC

Explains how default DSCP (Differentiated Services Code Point) values are applied within Application Visibility and Control (AVC).

Configuring default DSCP for AVC profile (GUI)

Configure default DSCP for AVC profile using GUI.

Assign a default DSCP value for an Application Visibility and Control (AVC) profile using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **QoS**.
2. Click **Add**.
3. Enter the **Policy Name**.
4. Click **Add Class-Maps**.
5. Select **AVC** from the **AVC/User Defined** drop-down list.
6. Click either **Any** or **All** match type radio button.
7. Select **DSCP** from the **Mark Type** drop-down list.
8. a) Check the **Drop** check box to drop traffic from specific sources.
   b) If you do not want to drop the traffic, enter the **Police(kbps)** and select the match type from the **Match Type** drop-down list. Choose the items from the available list and click move them to the selected list. Click **Save**.
9. Click **Apply to Device**.

Guidelines to configure default DSCP marking for unclassified AVC packets

Configure Default DSCP for AVC Profile.

When using Cisco Catalyst 9800 Series Wireless Controller or , ensure you configure a default DSCP marking for packets not matched by AVC policy filters. This allows consistent QoS treatment, even when your policy exceeds the 32-filter limit or cannot individually classify certain packet types.

- Set a default marking action in your class map and policy map to handle all unclassified traffic.
- Apply this configuration to ensure unclassified packets receive the intended QoS treatment.

Create class map (CLI)

Create class map using commands.

Define a class map to identify and categorize network traffic based on application names, categories, subcategories, or application groups.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a class map.

   Example

   ```
   Device(config-pmap)# class-map avc-class
   ```

3. Specify match to the application name, category name, subcategory name, or application group.

   Example

   ```
   Device(config)# class-map avc-class
   Device(config-cmap)# match protocol avc-media
   Device(config)# class-map class-avc-category
   Device(config-cmap)# match protocol attribute category avc-media

   Device# class-map class-avc-sub-category
   Device(config-cmap)# match protocol attribute sub-category avc-media

   Device# class-map avcS-webex-application-group
   Device(config-cmap)# match protocol attribute application-group webex-media
   ```

4. Return to privileged EXEC mode. Alternatively, press Ctrl-Z to exit global configuration mode.

   Example

   ```
   Device(config)# end
   ```

Create policy map (CLI)

Create policy map using commands.

Define and configure a policy map in global configuration mode to classify and act on network traffic.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Create a policy map by entering the policy map name to enter policy-map configuration mode.

Example

```
Device(config)# policy-map avc-policy
```

By default, no policy maps are defined.

When a policy map is used, it sets the DSCP to zero for IP packets and sets the CoS to zero for tagged packets.

> **Note**
>
> To delete an existing policy map, use the no policy-map policy-map-name global configuration command.

3. Define a traffic classification to enter policy-map class configuration mode.

Example

```
Device(config-pmap)# class [class-map-name | class-default]
```

By default, no policy maps or class maps are defined.

If a traffic class has already been defined by using the class-map global configuration command, specify its name as class-map-name in this command.

The class-default traffic class is predefined and can be added to any policy. It is always placed at the end of a policy map. The class-default class includes an implied 'match any,' which ensures that all packets that have not already matched other traffic classes are matched by class-default.

> **Note**
>
> To delete an existing class map, use the no class class-map-name policy-map configuration command.

4. Classify IP traffic by setting a new value in the packet.

Example

```
Device(config-pmap-c)# set dscp new-dscp 45
```

For **dscp new-dscp** , enter a new DSCP value to assign to the classified traffic. The range is zero to 63.

5. Specify the default class so that you can configure or modify its policy.

Example

```
Device(config-pmap)# class class-default
```

6. Configure the default DSCP.

Example

```
Device(config-pmap)# set dscp default
```

7. Return to privileged EXEC mode. Alternatively, press Ctrl-Z to exit global configuration mode.

Example

```
Device(config-pmap)# end
```

AVC-based selective reanchoring

Explains how AVC-based selective reanchorings manage client mobility between wireless controllers based on application traffic and AVC profiles.

An AVC-based selective reanchoring is a wireless client mobility mechanism that

- reanchors clients as they roam between one controller to another and prevent depletion of available IP addresses, and
- uses AVC profile-based statistics to determine if a client should be reanchored or deferred.

This is useful when a client is actively running a voice or video application defined in the AVC rules.

The reanchoring process also involves deauthentication of anchored clients. The clients get deauthenticated when they do not transmit traffic for the applications listed in the AVC rules while roaming between controllers.

Restrictions for AVC-based selective reanchoring

AVC-based selective reanchoring restrictions.

- This feature operates only in local mode. FlexConnect and fabric modes are not supported.
- This feature does not operate in guest tunneling scenarios or export anchor scenarios.
- After reanchoring, the old IP address is retained until the IP address lease period ends.

Configure the flow exporter (CLI)

Configure the flow exporter using commands.

Define and configure a flow exporter to specify where and how NetFlow data is exported from the device.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Create a flow exporter and enter the flow exporter configuration mode.

   Example

   ```
   Device(config)# flow exporter avc-reanchor
   ```

   Note

   You can use this command to modify an existing flow exporter too.

3. Set the exporter as local.

   Example

   ```
   Device(config-flow-exporter)# destination local wlc
   ```

Configure the flow monitor (CLI)

Configure the flow monitor using commands.

Set up a flexible NetFlow flow monitor to track traffic statistics.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a flow monitor and enter the flexible NetFlow flow monitor configuration mode.

   Example

   ```
   Device(config)# flow monitor fm_avc
   ```

   Note

   You can use this command to modify an existing flow monitor too.

3. Specify the name of an exporter.

Example

```
Device(config-flow-monitor)# exporter avc-reanchor
```

4. Specify the flow record to use to define the cache.

Example

```
Device(config-flow-monitor)# record wireless avc basic
```

5. Set the active flow timeout, in seconds.

Example

```
Device(config-flow-monitor)# cache timeout active 60
```

6. Set the inactive flow timeout, in seconds.

Example

```
Device(config-flow-monitor)# cache timeout inactive 60
```

Configure the AVC reanchoring profile (CLI)

Configure the AVC reanchoring profile using commands.

Configure traffic reanchoring for AVC by creating and updating an AVC reanchoring profile using commands.

Before you begin

- Ensure that you use the AVC-Reanchor-Class class map. All other class-map names are ignored by Selective Reanchoring.
- During boot up, the system checks for the existence of the AVC-Reanchor-Class class map. If it is not found, the system creates default protocols, such as jabber-video, WiFi-calling, and others. If the AVC-Reanchor-Class class map is found, configuration changes are not made. Updates to protocols saved to the startup configuration persist across reboots.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the class map.

Example

```
Device(config)# class-map AVC-Reanchor-Class
```

3. Instruct the device to match with any of the protocols that pass through it.

   Example

   ```
   Device(config-cmap)# match any
   ```

4. Specify a match to the application name.

   Example

   ```
   Device(config-cmap)# match protocol jabber-audio
   ```

   You can edit the class-map configuration later to add or remove protocols such as **jabber-video and wifi-calling** if needed.

Configure the wireless WLAN profile policy (CLI)

Configure the wireless WLAN profile policy using commands.

Follow the procedure given below to configure the WLAN profile policy.

> **Note**
>
> Starting with Cisco IOS XE Amsterdam 17.1.1, IPv6 flow monitor is supported on Wave 2 APs. When NBAR runs in the controller and the AP operates in local (central switching) mode, you can attach two flow monitors per direction (input and output) and per IP version (IPv4 and IPv6) in a policy profile. In FlexConnect and fabric modes on Wave 2 APs, when NBAR runs on the AP, only one flow monitor per direction (input and output) and per IP version (IPv4 and IPv6) is supported.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile and enters wireless policy configuration mode and disable the policy profile.

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

   ```
   Device(config-wireless-policy)# shutdown
   ```

3. Disable central switching.

Example

```
Device(config-wireless-policy)# no central switching
```

4. Specify the name of the IPv4 ingress flow monitor.

Example

```
Device(config-wireless-policy)# ipv4 flow monitor fm_avc input
```

5. Specify the name of the IPv4 egress flow monitor.

Example

```
Device(config-wireless-policy)# ipv4 flow monitor fm_avc output
```

6. Specify the name of the IPv6 ingress and egress flow monitor.

Example

```
Device(config-wireless-policy)# ipv6 flow monitor fm_v6_avc input
```

```
Device(config-wireless-policy)# ipv6 flow monitor fm_v6_avc output
```

7. Enable the policy profile.

Example

```
Device(config-wireless-policy)# no shutdown
```

Verify AVC reanchoring

Verify AVC reanchoring.

Use the commands to verify the AVC reanchoring configuration:

```
Device# show wireless profile policy detailed avc_reanchor_policy

Policy Profile Name           : avc_reanchor_policy
Description                   :

81 Software-Defined Application Visibility and Control

Topics:

- Software-defined application visibility and control
- List of package files

Software-defined application visibility and control

Introduces Software-Defined Application Visibility and Control (SD-AVC), detailing its centralized analytics, anomaly detection, per-WLAN configuration, integration with NBAR, platform and release support for IPv4/IPv6, and the associated feature history and commands for enterprise network traffic management.

A software-defined application visibility and control system is a network-level application visibility and control (AVC) controller that

- aggregates application data from multiple devices and sources
- provides composite analytics and telemetry on enterprise network traffic, and
- enables centralized deployment and management of protocol pack updates.

SD-AVC recognizes most enterprise network traffic and provides analytics, visibility, and telemetry into application recognition on the network. SD-AVC profiles all endpoints connected to access nodes, including wireless bridged virtual machines, to perform anomaly detection operations such as Network Address Translation (NAT). SD-AVC alerts you when the same MAC address is used at the same time on different networks.

You can enable the Software-Defined Application Visibility and Control feature on a per-WLAN basis. You can enable or disable Software-Defined Application Visibility and Control functionalities independently.

> **Note**
>
> Restart the Capwapd process or reload the AP to resume SD-AVC operation after the SD-AVC process (stilepd) crashes.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 86: Feature history for Software-defined application visibility and control

Feature Name	Release Information	Feature Description
Software-defined application visibility and control (SD-AVC) wireless support with IPv6	Cisco IOS XE 17.18.1	From Cisco IOS XE 17.18.1 onwards, this feature extends the support for adding IPv6 SD-AVC controller or end-point address. These platforms are supported: • Cisco Catalyst 9800 controllers: 9800-40, 9800-80, 9800-L, 9800-CL, 9800-SW, CW9800M, CW9800H1, and CW9800H2. • Cisco Catalyst 9300/9400 switches in Fabric mode. • Cisco Wave 2, Wi-Fi 6/6E, and Wi-Fi 7 APs. SD-AVC IPv6 is not supported on Cisco Wireless AireOS Controllers, Cisco Embedded Wireless Controller on Catalyst APs, and Cisco Wave 1 APs.
Software-defined application visibility and control (SD-AVC) wireless support with IPv4	Cisco IOS XE 17.17.1	From Cisco IOS XE 17.17.1 onwards, this feature extends the support for adding the AP and controller payload code for only IPv4 SD-AVC addresses.
Software-defined application visibility and control	Cisco IOS XE 17.7.1	Software-Defined AVC aggregates application data from multiple sources and provides composite application information. These commands are introduced: • address and avcsd-service • controller and destination-ports • dscp • segment • source-interface • transport and application-updates • vrf and showsdavc ap download status • showsdavc status ap

Supported platforms for SD-AVC IPv6

This topic lists the platforms that support the SD-AVC IPv6 feature.

- Cisco Catalyst 9800 controllers-9800-40, 9800-80, 9800-L, 9800-CL, and 9800-SW.
- Cisco Catalyst 9300/9400 switches in Fabric mode.
- Cisco Wave 2 and 11AX APs.

Non supported platforms for SD-AVC IPv6

- Cisco Wireless AireOS Controllers.
- Cisco Embedded Wireless Controller on Catalyst APs.
- Cisco Wave 1 APs

Enable software-defined application visibility and control on a WLAN (CLI)

Enable software-defined application visibility and control on a WLAN using commands.

Allow the system to recognize and manage applications on a WLAN by enabling software-defined application visibility and control using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy test-policy-profile
   ```

3. Disable central switching and enable local switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

4. Enable application recognition on the wireless policy profile by activating the NBAR2 engine.

   Example

   ```
   Device(config-wireless-policy)# ip nbar protocol-discovery
   ```

5. Exit wireless policy configuration mode and return to the privileged EXEC mode.

   Example

   ```
   Device(config-wireless-policy)# end
   ```

Configure software-defined application visibility and control global parameters (CLI)

Configure software-defined application visibility and control global parameters using commands.

Enable SD-AVC globally and configure connectivity parameters for SD-AVC controllers using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable SD-AVC and enter the software-definition service configuration mode.

   Example

   ```
   Device(config-sd-service)# avc sd-service
   ```

3. Configure a segment name identifying a group of devices sharing the same application services.

   Example

   ```
   Device(config-sd-service)# segment AppRecognition
   ```

4. Enter SD service controller configuration mode to configure connectivity parameters.

   Example

   ```
   Device(config-sd-service)# controller
   ```

5. Configure controller IP address. Supports only IPv4 address.

   Example

   ```
   Device(config-sd-service-controller)# address 209.165.201.0
   ```

6. Configure the destination port for communicating with the controller.

   Example

   ```
   Device(config-sd-service-controller)# destination-ports sensor-exporter 21730
   ```

7. Enable DSCP marking and configure source interface for communicating with the controller.

   Example

   ```
   Device(config-sd-service-controller)# dscp 16
   ```

   ```
   Device(config-sd-service-controller)# source-interface GigabitEthernet21
   ```

8. Configure transport protocols for communicating with the controller and associate the VRF with the source interface.

Example

```
Device(config-sd-service-controller)# transport application-updates https
url-prefix cisco
```

```
Device(config-sd-service-controller)# vrf doc-test
```

9. Exit the SD service controller configuration mode and enter the privileged EXEC mode.

Example

```
Device(config-sd-service-controller)# end
```

List of package files

Displays the list of package files that are received by the controller from the SD-AVC.

To view the list of package files list that are sent from the SD-AVC to the controller, use the following command:

```
Device# dir bootflash:sdavc
Directory of bootflash:/sdavc/

251671  -rw-             6728  Jun 26 2025 03:26:54 +00:00  sdavc_config.json
251674  -rw-              338  Jun 26 2025 03:21:55 +00:00
import_file_meta.json

11250098176 bytes total (3345641472 bytes free)
```

Verify SD-AVC controller connection status

This content displays the verification output for the SD-AVC and controller connection status.

To display the SD-AVC connection status and information summary in the controller, run the **show avc sd-service info summary** command.

```
Device# show avc sd-service info summary
Status: CONNECTED
Device ID: SDA_BOX
Device segment name: C9400_HA
Device address: 192.0.2.1
Device OS version: 17.18.01prd15
Device type: C9407R
Active controller:
   Type    : Primary
   Address : 192.0.2.1
   Status  : Connected
   Version : 4.4.0
```

```
   Last connection: 06:21:35.000 UTC Thu Jun 19 2025
Active SDAVC import files:
    Protocol pack:          Not loaded
    Secondary protocol pack: PPDK_C9400_HA_00a38d1dddb4fa0bc4b51f91f97744.pack

    Rules pack:             pp_update_C9400_HA_a_v2_b32d0890d8a3.pack
```

Verify SD-AVC details in AP

Verify SD-AVC package files in flash

To verify the protocol files received from the controller, run the **show flash sdavc-pkg** command in the AP.

```
Cisco-AP# show flash sdavc-pkg
Files under /usr/bin/sdavc/
total 36K
drwxr-xr-x    2 Cisco    root           40 Jun 19 06:10 container_application

82 Cisco Hyperlocation

Topics:

- Cisco Hyperlocation
- NTPS and BLE configuration

Cisco Hyperlocation

Explains how Cisco Hyperlocation solutions use specialized radio modules and algorithms to achieve precise real-time locating of Wi-Fi and BLE devices, supporting advanced asset tracking and targeted content delivery in wireless environments.

A hyperlocation solution is a wireless location technology that

- uses specialized radio modules and algorithms to pinpoint the real-time position of Wi-Fi and BLE devices
- enables advanced asset tracking and targeted content delivery by achieving sub-meter location accuracy, and
- integrates with wireless network infrastructure and management platforms (such as controller and CMX)

You can use the Cisco Hyperlocation radio module in Cisco Aironet 3600, 3700, and 4800 Series APs to enable hyperlocation.

Hyperlocation is also supported in Fabric mode. In particular, when the wireless controller runs on the switch, the controller provisions the APs. The APs generate Hyperlocation VxLAN packets that can travel across the fabric network. The network infrastructure delivers these packets to the CMX destination.

The Hyperlocation VxLAN packets are special packets marked with SGT 0 and use the L3VNID of the APs. For more information, refer to the SDA documentation.

The Cisco Hyperlocation radio module provides these functions:

- WSM or WSM2 radio module functions extended to support:
  - 802.11ac
  - Wi-Fi Transmit
  - 20-MHz, 40-MHz, and 80-MHz channel bandwidth.
- Expanded location functionality:
  - Low-latency location optimized channel scanning
  - 32-antenna angle of arrival (AoA); available only with the WSM2 module.

Using the controller, you can configure Cisco Hyperlocation for APs based on their profile.

Note

When you use the WSM2 module (which includes the WSM module and the antenna add-on), the accuracy of tracking the location of wireless clients can be as close as one meter.

Cisco Hyperlocation works with Cisco Connected Mobile Experiences (CMX). When you combine the Cisco Hyperlocation feature on a Cisco Catalyst 9800 Series Wireless Controller with a CMX device, you can achieve better location accuracy, enabling more targeted content delivery to users. With CMX and Cisco CleanAir frequency scanning, it is easy to locate failed, lost, and rogue beacons.

The Cisco Hyperlocation radio module with an integrated BLE radio allows transmission of Bluetooth Low Energy (BLE) broadcast messages by using up to five BLE transmitters. The Cisco Catalyst 9800 Series Wireless Controller configures transmission parameters, such as the beacon interval, universally unique identifier (UUID), and transmission power for each beacon, globally for all APs. You must enable the Cisco Hyperlocation feature on the controller. The controller configures the major, minor, and transmission power values for each AP to provide more beacon granularity.

> **Note**
>
> The Cisco Hyperlocation feature must be enabled on the controller. In addition, CMX must be connected for BLE to work.

If a Cisco Hyperlocation radio module is not present, you can use *Hyperlocation Local Mode*. This option provides location accuracy between five and seven meters by using CPU cycle stealing.

Restrictions on Cisco Hyperlocation

Cisco Hyperlocation restrictions.

- You cannot modify detection, trigger, or reset thresholds while Hyperlocation is enabled.
- You can set the reset threshold to any value from zero up to one less than the current threshold. For example, if the reset threshold is 10, set it to any value from 0 to 9.
- Ensure that CMX is reachable through an SVI interface (VLAN) when you run Cisco Hyperlocation on the Cisco Catalyst 9800 Series Wireless Controller in a non-Fabric deployment. If CMX is reachable only through an L3 port, an error occurs.
- In Fabric deployments, do not place the wireless management interface (typically a loopback interface) in Fabric.
- You cannot assign the wireless management interface to a loopback interface in non-Fabric deployments.

Configure Cisco Hyperlocation (GUI)

Configure Cisco Hyperlocation using GUI.

Enable and configure Cisco Hyperlocation to achieve high-accuracy wireless client location tracking.

Cisco Hyperlocation is a location solution that allows you to track the location of wireless clients with an accuracy of one meter. When you select this option, all other fields on the screen are disabled except for NTP Server.

Procedure

1. Choose **Configuration > Tags & Profiles > AP Join**. Click **Add**.

   The **Add AP Join Profile** dialog box appears.
2. Under the **AP** > **Hyperlocation** tab, check the **Enable Hyperlocation** check box.
3. In the **Detection Threshold (dBm)** field, enter a value to filter out packets with low RSSI. The valid value range is between -100 dBm and -50 dBm.
4. In the **Trigger Threshold (cycles)** field, enter a value to set the number of scan cycles before sending a BAR to clients. The valid value range is between 0 and 99.
5. In the **Reset Threshold is required** field, enter a value to reset value in scan cycles after trigger. The valid value range is between 0 and 99.
6. Click **Save & Apply to Device**.

Configure Cisco Hyperlocation (CLI)

Configure Cisco Hyperlocation using commands.

Enable and customize Cisco Hyperlocation features on supported APs using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Enable Cisco Hyperlocation feature on all the supported APs that are associated with this AP profile.

   Example

   ```
   Device(config-ap-profile)# hyperlocation
   ```

   Use the **no** form of the command to disable the Cisco Hyperlocation feature.

4. Set threshold to filter out packets with low RSSI.

   Example

   ```
   Device(config-ap-profile)# hyperlocation threshold detection -100
   ```

   The **no** form of this command resets the threshold to its default value. The valid value range is between -100 and -50.

5. Reset the value of scan cycles after a trigger.

   Example

   ```
   Device(config-ap-profile)# hyperlocation threshold reset 8
   ```

   The **no** form of this command resets the threshold to its default value.

6. Set the number of scan cycles before sending a block acknowledgment request (BAR) to clients.

   Example

   ```
   Device(config-ap-profile)# hyperlocation threshold trigger 10
   ```

   The **no** form of this command resets the threshold to its default value.

7. Set the IP address of the NTP server.

   Example

   ```
   Device(config-ap-profile)# ntp ip 9.0.0.4
   ```

The **no** form of this command removes the NTP server.

Verify Cisco Hyperlocation

Verify Cisco Hyperlocation.

To display the hyperlocation status values and parameters for all the AP profiles, use this command:

```
Device# show ap hyperlocation summary

Profile Name: custom-profile
Hyperlocation operational status: Down
Reason: Hyperlocation is administratively disabled
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Disabled
Hyperlocation detection threshold (dBm): -100
Hyperlocation trigger threshold: 10
Hyperlocation reset threshold: 8
Profile Name: default-ap-profile
Hyperlocation operational status: Up
Reason: N/A
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -90
Hyperlocation trigger threshold: 22
Hyperlocation reset threshold: 8
```

To display both the overall and the per-AP configuration values and operational status, use this command:

```
Device# show ap hyperlocation detail

Profile Name: house24
Hyperlocation operational status: Up
 Reason: NTP server is not properly configured
Hyperlocation NTP server: 198.51.100.1
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -90
Hyperlocation trigger threshold: 8
Hyperlocation reset threshold: 7
AP Name                 Radio MAC         Method      CMX IP            AP
Profile
-----------------------------------------------------------------------------------------
APe865.49d9.bfe0        e865.49ea.a4b0    WSM2+Ant    198.51.100.2
house24
APa89d.21b9.69d0        a89d.21b9.69d0    Local       198.51.100.3
house24
APe4aa.5d3f.d750        e4aa.5d5f.3630    WSM         198.51.100.4
house24
```

To display the overall (profile specific) configuration values and operational status for a given profile, use this command:

```
Device# show ap profile profile-name hyperlocation summary

Profile Name:
               profile-name
Hyperlocation operational status: Up
   Reason: N/A
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Enabled
```

```
Hyperlocation detection threshold (dBm): -100
Hyperlocation trigger threshold: 10
Hyperlocation reset threshold: 8
```

To display both the overall (profile specific) and per-AP configuration values and operational status for a given profile, use this command. The APs listed are only those APs that belong to the specified join profile.

```
Device# show ap profile profile-name hyperlocation detail

Profile Name:
                profile-name
Hyperlocation operational status: Up
 Reason: N/A
Hyperlocation NTP server: 209.165.200.224
Hyperlocation admin status: Enabled
Hyperlocation detection threshold (dBm): -90
Hyperlocation trigger threshold: 8
Hyperlocation reset threshold: 7
AP Name                 Radio MAC         Method      CMX IP
-----------------------------------------------------------------
APf07f.0635.2d40        f07f.0635.2d40    WSM2+Ant    198.51.100.2
APf07f.0635.2d41        f07f.0635.2d41    Local       198.51.100.3
APf07f.0635.2d42        f07f.0635.2d42    WSM         198.51.100.4
```

To display configuration values for an AP profile, use this command:

```
Device# show ap profile profile-name detailed

Hyperlocation :
  Admin State             : ENABLED
  PAK RSSI Threshold Detection: -100
  PAK RSSI Threshold Trigger  : 10
  PAK RSSI Threshold Reset    : 8
.
.
.
```

To display the Cisco CMXs that are correctly joined and used by hyperlocation, use this command:

```
Device# show ap hyperlocation cmx summary

Hyperlocation-enabled CMXs
IP            Port Dest MAC        Egress src MAC Egress VLAN Ingress src MAC
 Join time
-------------------------------------------------------------------------------------------
198.51.100.4  2003 aaaa.bbbb.cccc  aabb.ccdd.eeff 2           0000.0001.0001
 12/14/18 09:27:14
```

To display the hyperlocation client statistics, use this command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient
cpp-client summary

Client Type Abbreviations:
  RG - REGULAR BL - BLE
  HL - HALO    LI - LWFL INT
Auth State Abbreviations:
  UK - UNKNOWN IP - LEARN IP IV - INVALID
  L3 - L3 AUTH RN - RUN
Mobility State Abbreviations:
  UK - UNKNOWN IN - INIT
```

```
  LC - LOCAL   AN - ANCHOR
  FR - FOREIGN MT - MTE
  IV - INVALID
EoGRE Abbreviations:
  N - NON EOGRE Y - EOGRE
 CPP IF_H     DPIDX      MAC Address    VLAN  CT  MCVL  AS  MS  E  WLAN POA
------------------------------------------------------------------------------

   0X32     0XF0000001  0000.0001.0001   9    HL   0    RN  LC  N       NULL
```

To display the interface handle value statistics, use this command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient
datapath cpp-if-handle 0x32 statistics start
```

To display the recorded flow, use this command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient
datapath cpp-if-handle 0X32 statistics

                    Pkts                Bytes
Rx                   26                 3628
```

To stop statistics capture, use this command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient
datapath cpp-if-handle 0x32 statistics stop
```

To display the APs requested by Cisco CMX with AP group support, use this command:

```
Device# show nmsp subscription group summary

CMX IP address: 198.51.100.4
  Groups subscribed by this CMX server:
  Group name: CMX_1198.51.100.4
Device# show nmsp subscription group detail ap-list CMX_198.51.100.1
198.51.100.1

CMX IP address: 198.51.100.1
CMX Group name: CMX_198.51.100.1
CMX Group AP MACs:
: aa:bb:cc:dd:ee:01 aa:bb:cc:dd:ee:02 aa:bb:cc:dd:ee:03 aa:bb:cc:dd:ee:03
```

To display the NTP IP address and authentication parameters, use this command:

```
Device# show ap profile profile-name detailed

.
.
.
NTP Authentication : ENABLED
Key id : 2
Key type : SHA1
Key format : HEX
Key : 3a2275c74c250c362ca63e4af06fa3f3cd8d4aec
Encryption type : Clear
.
.
.
```

To display the NTP status for each AP, use this command:

```
Device# show ap name AP-G1-230 ntp status

ap-name       enabled v4/v6 IPAddress       Status     Stratum LastSync
SyncOffset
AP-G1-230     Y       v4    198.51.100.5    AuthFail   4       1000      100
```

To display NTP status for all the APs, use this command:

```
Device# show ap ntp status

ap-name       enabled v4/v6 IPAddress  Status  Stratum LastSync  SyncOffset
AP-G1-230         Y      v4   5.5.5.5  AuthFail 2        Never
AP-G1-231         Y      v4   5.5.5.10  Synced  3        1000       100
AP-G1-232         Y      v4   5.5.5.15  Synced  16       2000        50
```

To display the instant status of NTP synchronization for an AP, use this command. The output is from an AP and not from the controller.

```
Device# show ntp

!This error message is displayed when NTP is not configured.
%Error: ntpd is not running
!The following output is displayed when NTP is configured.
Stratum  Version  Last Received    Delay     Offset    Jitter   NTP server
13       4        7sec ago         1.124ms   0.536ms   0.001ms  198.51.100.5
```

To display AP timezone information, use this command:

```
Device# show ap timezone

AP Name   Status   Offsets(h/m)
-------------------------
AP1      Disabled    0:0
AP2      Enabled     1:0
```

NTPS and BLE configuration

Explains how NTP servers provide accurate time synchronization for network devices and ensure the operation of Cisco Hyperlocation services and describes how BLE configurations enable flexible beacon management for access points using per-AP profile and per-AP settings.

A network time protocol server is a network device that

- provides authoritative time information to other devices on the network, and
- enables accurate time synchronization across distributed systems and applications.

For Cisco Hyperlocation to work, synchronize the AP with accurate time. The controller sends NTP information to the AP to achieve this synchronization. The AP then uses the NTP server to synchronize its clock. Therefore, the AP needs connectivity to the NTP server.

APs can be geographically dispersed. Therefore, it is necessary to provide different NTP servers to different APs. Configure NTP server information for each AP profile. If you do not configure NTP information on the AP profile, the controller uses one of the global NTP peers in its configuration. If the controller acts as an NTP server, it uses its management IP address for synchronization. If the NTP server is unavailable, Cisco Hyperlocation is disabled.

> **Note**
>
> In scale setup, the NTP server should be configured on the respective AP profiles, so that the APs and CA servers used for LSC provisioning are time synchronized. If the NTP server is not configured, a few APs would fail in LSC provisioning.

Bluetooth Low Energy Configuration

The BLE configuration is split into two parts: per-AP profile and per AP. You can configure the BLE feature partially from the AP profile (by default, the AP profile BLE configuration is applied) and partially per AP (some or all the attributes are applied).

Table 87: BLE Configuration Details

Attribute	BLE Configuration Per AP Profile	BLE Configuration Per AP
Attributes with per-AP granularity (global for all the beacons)	• Interval • Advertised transmission power	• Interval • Advertised transmission power
Attributes with per-AP per0-beacon granularity	• Transmission power • UUID • Status	• Transmission power • UUID • Status • Major • Minor

> **Note**
>
> The *default-ap-profile* BLE configuration serves as the default BLE configuration because all APs join the *default-ap-profile* AP profile if the other profiles are removed.
>
> For more information about Cisco Hyperlocation, see the following documents:
>
> - Cisco Hyperlocation Solution
> - Cisco CMX Configuration Guide to enable Cisco Hyperlocation
> - Cisco CMX Release Notes

Best practices for NTP configuration

Follow these best practices when configuring NTP :

- Configure multiple redundant NTP time sources to avoid reliance on a single server and improve reliability.
- Use a loopback interface as the NTP source for consistency across device reboots and interface changes.
- Enable NTP authentication to secure communications and prevent malicious time alterations.

- Monitor NTP status and logs regularly; implement detection and alerting mechanisms using commands like **show ntp status** and **show ntp associations**.
- Use the **ntp panic-threshold-apply** command to check the configuration sanity checks, which reject large clock changes and prevent network instability.
- Address failure modes related to time-based authentication keychains by configuring overlapping key lifetimes to avoid routing disruptions.
- Regularly monitor and validate NTP synchronization status with monitoring tools and SNMP traps.
- Ensure operational practices include multiple NTP sources and configuration checks to prevent routing disruptions caused by time inaccuracies.

These practices help maintain accurate time synchronization, improve NTP security, and minimize the risk of network instability caused by incorrect time settings.

AP group NTP server

AP group NTP server details.

An AP group NTP server is a time synchronization mechanism that

- ensures precise time alignment across all APs within an AP group to achieve location accuracy
- reduces synchronization delays compared to using a WAN-based global NTP server, and
- supports features that rely on accurate timing, such as Cisco Hyperlocation, BLE AoA, and Intelligent Capture.

If your controller and global NTP server are configured on the WAN, the APs may experience significant synchronization delays. These delays can reduce location accuracy.

When all APs in a group synchronize with the same NTP server, you can obtain accurate data for location calculations. Configure the NTP server locally for all APs in an AP group to improve synchronization among the APs.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 88: Feature history for AP group NTP server

Feature Name	Release Information	Feature Description
AP group NTP server	Cisco IOS XE 17.6.1	From this release, the global NTP server configuration is replaced with per-AP-group NTP server configuration. Per-group NTP is now required for the Cisco Hyperlocation feature. These commands are introduced: • ntpauth-key • timezonedelta • timezoneuse-controller • showap name ntp status • showap ntp status • showap timezone

Configure an AP group NTP server (CLI)

Configure an AP group NTP server using commands.

Set a Network Time Protocol (NTP) server for AP groups to ensure time synchronization.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Set the IP address of the NTP server.

   Example

   ```
   Device(config-ap-profile)# [no] ntp ip 9.0.0.4
   ```

   The **no** form of this command removes the NTP server.

4. Configure the NTP server per AP profile to support authentication.

Example

```
Device(config-ap-profile)# [no] ntp auth-key index type type format format
key encryption-type server-key
```

The **no ntp auth-key** command removes the NTP server from each AP profile.

> **Note**
>
> For an ASCII key, ensure that the length is fewer than 21 bytes. For a HEX key, the length must be fewer than 41 bytes and can use only numbers from 0-9 and characters a-f.

Configure AP timezone (CLI)

Configure AP Timezone using commands.

Set the correct timezone for APs to ensure accurate time-stamping and scheduling using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile test
   ```

3. Configure the timezone offset for AP.

   Example

   ```
   Device(config-ap-profile)# timezone {use-controller | delta hour -12 | minute
    2}
   ```

   You can configure the AP timezone for each AP profile only. It is not possible to configure the timezone for individual APs.

   To configure the timezone, you can either apply the current controller timezone or specify the time difference. By default, timezone is disabled.

BLE concurrent scanning and beaconing

BLE concurrent scanning and beaconing details.

A BLE concurrent scan and beacon feature is a wireless AP capability that

- enables the BLE radio on an AP to scan for device signals and transmit beacons simultaneously
- allows the radio to temporarily pause and return to scanning while sending beacon transmissions, and
- supports seamless switching between scanning and beaconing operations to maximize BLE functionality.

To enable BLE concurrent scanning and beaconing, use Cisco Spaces and select **Dual** mode under **Device Management > AP Beacon > Settings**.

> **Note**
>
> If you use v-IBeacon, BLE concurrent scanning and beaconing is not supported. Supported advertisement profiles are iBeacon, Eddystone-URL, and Eddystone-UID.

Supported APs

This feature is supported only on:

- Cisco Catalyst 9105AX APs.
- Cisco Catalyst 9120AX APs.
- Cisco Catalyst 9124AX APs.
- Cisco Catalyst 9130AX APs.
- Cisco Catalyst 9136AX APs.
- Cisco Catalyst 916X APs.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 89: Feature history for BLE concurrent scanning and beaconing

Feature Name	Release Information	Feature Description
BLE concurrent scanning and beaconing	Cisco IOS XE 17.9.1	From this release, BLE concurrent scanning and beaconing is supported on Cisco Catalyst Wi-Fi 6 APs in basic mode or Cisco IOx mode. The BLE radio on an AP can stop a scan for beacon transmission, and return to the scan after completing the beacon transmission.

Verify BLE concurrent scanning and beaconing

Verify BLE concurrent scanning and beaconing.

Use these commands to verify the status of concurrent scanning and beaconing.

To display the advertisement profile, scan counters, advertisement counters, and other information, enter this command from the AP console:

```
Device# show controllers IOTRadio ble 0 interface
Active BLE host interface       : /dev/ttyiot0
BLE Radio Status                : Powered on
Device Status                   : Open
Device Mode                     : Native
Device resets                   : 4
Last Reset Reason               : Watchdog Timer Reset
Heart beat status               : On
                Scan Status : Enabled Active Transmit Profile : Eddystone URL
BLE MAC                         : 80:6F:B0:31:EF:74
Transmitted advertisement count
 since BLE enabled              : 0
Total scan records received     : 3617
```

To determine whether the transmit profile configuration was successfully pushed from Cisco Spaces to the AP, enter this command from the AP console:

```
Device# show controllers iOTRadio ble 0 broadcast
BLE Profile Config

83 FastLocate for Cisco Catalyst Series Access Points

Topics:

- FastLocate

FastLocate

Introduces FastLocate technology, detailing deployment restrictions, compatible access points, core network components and functions, step-by-step GUI-based configuration instructions, and verification procedures for effective location tracking with Cisco access points.

A FastLocate solution is a Wi-Fi location technology that

- collects received signal strength indication (RSSI) data or location data from data packets rather than probe requests
- increases the frequency of location updates, and
- improves the effectiveness of location-based services (LBS).

Feature history

Feature Name	Release	Description
FastLocate for Cisco Catalyst Series Access Points	Cisco IOS XE 17.1.1s	This feature enables higher location refresh rates by collecting RSSI or location information from data packets that APs receive. The network can then initiate location-based services (LBS) updates more frequently, leading to more accurate and timely device location tracking for Cisco Catalyst Series APs.

Traditional location tracking versus FastLocate

Traditional Wi-Fi location tracking relies on probe request messages from mobile devices. These probe requests are detected by multiple APs on different channels, and the RSSI or estimated location is sent to the APs to estimate the device's position.

However, Wi-Fi clients are increasingly probing less frequently to conserve battery life. Factors such as client type, operating system, driver, battery level, and current client activity influence how often a device sends probe requests, with intervals ranging from 10 seconds to five minutes. This inconsistency in probing leads to fewer data points and can affect the precision of real-world movement tracking.

FastLocate overcomes this limitation by using the more frequent data packets—rather than relying solely on probe requests—to collect RSSI and location data. These packets are aggregated by APs, enabling the network to initiate LBS updates more frequently and deliver higher location refresh rates.

Restriction for fabric deployments

Do not configure the Wireless Management Interface (WMI) as a loopback (Layer 3) interface in fabric deployments. Always use a VLAN interface for WMI to enable FastLocate functionality.

Supported access points

Supported Access Points for FastLocate.

To view all supported access points, see the AP Feature Matrix

Cisco Aironet 4800 Series also supports Hyperlocation using Angle of Arrival location calculation.

When you enable FastLocate on a supported AP

- the Cisco RF Application-specific integrated circuit (ASIC) radios act as a Wireless Services Software Interface (WSSI) module. The radios then switch to monitoring mode and to off-channel scanning mode.
- radios scan all 2.4-GHz and 5-GHz channels sequentially, spending 150 milliseconds (also called dwell time) on each channel, and
- RF ASIC radios synchronize with the NTP server. After each off-channel dwell period, FastPath sends all collected RSSI records in a specific packet format to the controller.

FastLocate network components and functions

Certain network components are essential for successful packet RSSI location computation using FastLocate.

Network Components	Functionality
Wireless clients	send data, management, and control packets.
Cisco Catalyst 9800 Series Wireless Controller	• configures NTP server data and location parameters on AP. • forwards RSSI information to Cisco CMX or Mobility Services Engine through FastPath or datapath.
Cisco Catalyst 9120 Series AP	• operates location radio in monitor or equivalent role. • synchronizes time with NTP server. • collects RSSI data from all clients (both associated and unassociated). • forwards this RSSI data to the controller through CAPWAP.
Cisco CMX	• parses Fastpath location data received from the controller. • computes client physical locations. • renders this position on the GUI using location algorithms.

Configure FastLocate (GUI)

Configure FastLocate using GUI.

Configure the AP join profile to enable FastLocate on your APs.

Use this task to activate FastLocate location services for APs managed by the controller.

Before you begin

Identify the AP join profile you wish to update.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.
2. On the **AP Join** window, click the **default-ap-profile** AP join profile.

3. In the **Edit AP Join Profile** window, click **AP**.
4. Under **Hyperlocation**, check the **Enable Hyperlocation**.
5. Click **Update & Apply to Device**.

Your selected AP join profile now has FastLocate (Hyperlocation) enabled and is applied to the device.

What to do next

Verify the configuration status and confirm location services are operating as expected.

Verify FastLocate

You can verify FastLocate on the controller and on APs.

Verify FastLocate on APs

```
Device# show ntp

Stratum   Version   Last Received   Delay    Offset    Jitter    NTP server
   1         4         123sec ago   1.169ms  -3.262ms  10.050ms    10.7.7.2
```

```
Device# show ap fast-path statistics

total packets sent   : 90001
invalid app ID drops : 0
application                  : 0 (HALO)
packets sent (CAPWAP)        : 90001
packets sent (APP HOST INTF) : 0
admin state drops            : 0
no dest IP drops             : 0
```

View FastLocate admin status details on the AP.

```
Device# show capwap client rcb

Hyperlocation Admin State    : Enabled
MSE Gateway MAC              : 00:50:56:86:0F:9D
WLC Hyperlocation Source Port: 9999
MSE IP Address               : 10.0.0.1
```

View FastPath related parameters on the AP such as source and destination IP addresses, port numbers, and the gateway MAC address.

```
Device# show ap fast-path configuration hyperlocation

source IP address     : 10.0.0.2
destination IP address: 10.0.0.1
source port (WLC)     : 9999
destination port (MSE): 2003
gateway MAC           : 00:50:56:86:0F:9D
ewlc hyperlocation MAC: 00:00:00:01:00:01
```

Verify FastLocate on Controller

View the summary of applications that send Fastpath or datapath data. The summary displays the hex code for the HyperLocation and BLE port numbers.

```
Device# show platform hardware chassis active qfp feature wireless wlclient cpp-client summary

Client Type Abbreviations:
RG - REGULAR     BL - BLE
HL - HALO        LI - LWFL INT
Auth State Abbreviations:

84 IoT Services Management

Topics:

- IoT services management

IoT services management

Explains how IoT services management automates device integration, connectivity, and data analytics in enterprise environments.

An IoT service is a network-enabled function that

- automates the integration and management of IoT devices within enterprise environments
- provides connectivity and control for a wide range of sensor and actuator devices, and
- supports real-time data collection and analytics for operational optimization.

Cisco Catalyst 9800 devices running the Cisco IOS XE image version 17.3.2 support Cisco Spaces: IoT Services along with the Network Assurance on Cisco Catalyst Center. IoT Services and Intelligent Capture (iCAP) port configuration are mutually exclusive.

If the iCAP feature is enabled on a device, IoT Services cannot be deployed. Conversely, if IoT Services is enabled, the iCAP feature cannot be deployed.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 90: Feature history for IoT services management

Feature Name	Release Information	Feature Description
BLE management on Cisco Catalyst 9136 Series APs	Cisco IOS XE 17.8.1	This feature allows Bluetooth Low Energy (BLE) management support in Cisco Catalyst 9136 Series APs.
Coexistence of intelligent capture (iCAP) or IoT Services - Dual gRPC channel	Cisco IOS XE 17.7.1	From Cisco IOS XE Cupertino 17.7.1, IoT services and iCAP port configurations may co-exist, creating two gRPC connections from the AP: one to Cisco Catalyst Center for iCAP, and one to Cisco Spaces Connector for IoT.
Assurance and IoT services coexistence without iCAP	Cisco IOS XE 17.3.2	From this release onwards, the controller supports deployment of both Cisco Catalyst Spaces IoT Services and network assurance on Cisco Catalyst Center. However, IoT Services and intelligent capture (iCAP) port configuration remain mutually exclusive.

gRPC connection configuration details

gRPC connection configuration details.

There are two gRPC connections from AP.

- One connection is to Cisco Catalyst Center for iCAP.
- The other connection is to Cisco Catalyst Center Connector for IoT Services.

The table lists configuration pairs that may or may not coexist on IOS-XE image versions 17.3.2.

Cisco DNA-C Configuration	Cisco Spaces Configuration	Coexistence on IOS-XE Image Version 17.3.2
network-assurance enable	**ap cisco-dna token** *token*	yes
network-assurance icap server port *port*	**ap cisco-dna token** *token*	no

Cisco Spaces: IoT Services is an end-to-end solution. You do not need to manually enable IoT services or Dot15 radio on the controller because Cisco Spaces automatically manages Dot15 radio. You can verify whether Dot15 radio is enabled from the controller interface.

Additionally, Cisco Spaces enables gRPC in the default *AP profile configuration*. Manual activation is not needed, but you can verify the settings on the controller.

Cisco Spaces also enables the *apphost* configuration, required for the default *AP profile* configuration. If Cisco Spaces does not enable *apphost*, you must enable it manually to host IOx applications on an AP.

Enable the 802.15 radio (CLI)

Enable the Dot15 radio using commands.

When you enable the BLE radio configuration globally, APs joined to the controller enable their BLE radio if they have the BLE radio chip in their hardware. This configuration applies to all APs that join the controller after you enable it.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable the dot15 radios for APs, globally.

   Example

   ```
   Device(config)# no ap dot15 shutdown
   ```

3. Disable the dot15 radio for all APs, globally.

   Example

   ```
   Device(config)# ap dot15 shutdown
   ```

Configure the gRPC token (CLI)

Configure the gRPC Token.

Configure the gRPC token so Cisco Spaces can push configuration and certificates to the controller using commands.

> **Note**
>
> - The configuration is pushed automatically from Cisco Spaces. You do not need to manually enable gRPC on the default *ap profile* configuration. You can verify the same on the controller
> - The NETCONF (NETCONF or YANG configuration) must be enabled on the device to allow Cisco Spaces to push the required configuration to the controller. Enable Secure Copy (**ip scp server enable**) on the controller to allow Cisco Spaces to push the gRPC certificate to the controller.
> - The iCAP server port configuration should not be present in the configuration. If the iCAP server port configuration exists, run the **iCAP server port zero** command.

Before you begin

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the Cisco Spaces gRPC token.

   Example

   ```
   Device(config)# ap cisco-dna token {0 | 8} cisco-token-number
   ```

   0 : Specifies the string as an UNENCRYPTED password.

   8 : Indicates the placeholder for backward compatibility.

Enable gRPC in an AP profile (CLI)

Enable gRPC in an AP profile using commands.

Currently, the Manage Streams feature of Cisco Spaces pushes the gRPC configuration only to the default AP profile. If you are using a different AP profile, you must manually configure gRPC.

This procedure explains how to enable gRPC on an AP profile that is not the default-ap-profile. Cisco Spaces may not push gRPC to all AP profiles. Use these commands to enable gRPC for individual AP profiles.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile-name
   ```

3. Enable the gRPC channel on the APs, in the AP profile.

   Example

   ```
   Device(config-ap-profile)# cisco-dna grpc
   ```

Verify BLE state and mode

Verify BLE state and mode.

To verify the BLE state and mode, run the command:

```
Device# show ap ble summary
AP Name          BLE AP State          BLE mode
-------------------------------------------------------------------------
Axel-1            Up                   Advanced (IOx)
Axel-2            Up                   Advanced (IOx)
9117-1            Up                   Advanced (IOx)
3800-1            Up                   Base (Native)
1815              Up                   Base (Native)
9120-3            Up                   Advanced (IOx)
9120-1            Up                   Base (Native)
9115-ax           Up                   Base (Native)
9120-2            Up                   Base (Native)
```

Verify BLE details

Verify BLE details.

To verify BLE details, run the command:

```
Device# show ap name APXXXX.BDXX.29XX ble detail
Mode report time          : 07/28/2020 09:40:57
Mode                      : Base (Native)

Verify gRPC summary, status, and statistics

Verify gRPC summary, status, and statistics.

To verify the gRPC summary, run the command:

```
Device# show ap grpc summary
AP Name              AP Mac             gRPC Status
-------------------------------------------------------------------------------

APXXXX.BDXX.F2XX     0cXX.bdXX.66XX     Up
```

To verify the packet statistics on the gRPC channel that also shows the transmit and receive failures, run the command:

```
Device# show ap name APXXXX.BDXX.F2XX grpc detail
gRPC channel status : Up
Packets transmit attempts : 62
Packets transmit failures : 0
Packets receive count : 62
Packets receive failures : 0
```

85 IoT Module Management in the Controller

Topics:

- IoT module management in the controller

IoT module management in the controller

Explains how IoT modules extend access points and centralize IoT application management through Cisco Catalyst Center.

An IoT module is a hardware extension for APs that

- connects to the controller via the USB interface for IoT integration, and
- supports provisioning, deployment and life cycle management of of third-party containerized applications, that act as containers through Cisco Catalyst Center on the APs.

After connecting the USB modules to the APs, log in to the controller and run commands to enable the USB modules and the Cisco IOx application in the APs associated with an AP profile group.

Supported APs

The IoT Module Management feature uses the USB interface to connect to the Cisco Internet of Things (IoT) connector on these APs:

- Cisco Catalyst 9105AXI
- Cisco Catalyst 9105AXW
- Cisco Catalyst 9115AX
- Cisco Catalyst 9117AX
- Cisco Catalyst 9120AX
- Cisco Catalyst 9130AX

Table 91: Feature history for IoT module management in the controller

Feature Name	Release Information	Feature Description
IoT module management in the controller	Cisco IOS XE 17.3.x	From this release, IoT Module Management enables Cisco Catalyst Series APs to connect IoT hardware modules via the USB interface. This feature allows provisioning, deployment, and lifecycle management of third-party containerized applications on the APs through Cisco Catalyst Center, using the Cisco IOx framework for seamless IoT integration and centralized management.

Enable a USB on the controller

Enable a USB on the controller using commands.

To enable a USB for all the APs connected in an AP profile and to enable Cisco IOx on all the APs, follow this procedure using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile-test
   ```

   Note

   You can use the default AP profile (default-ap-profile) or create a named AP profile, as shown in the example in the adjacent column.

3. Enable the apphost framework on Cisco APs.

   Example

   ```
   Device(config-ap-profile)# apphost
   ```

4. Enable a USB for Cisco APs.

   Example

   ```
   Device(config-ap-profile)# usb-enable
   ```

5. Exit the AP profile configuration mode.

   Example

   ```
   Device(config-ap-profile)# exit
   ```

6. Write running configuration to the memory.

   Example

   ```
   Device(config)# copy running-config startup-config
   ```

Verify the USB modules

Verify the USB modules.

To verify the state of USB modules, run the command:

```
Device# show ap config general
USB Module Type            : USB Module
USB Module State           : Enabled
USB Operational State      : Enabled
USB Override               : Disabled
```

To verify the apphost status, run the command:

```
Device# show ap apphost summary
AP Name                 AP Mac               Apphost Status            CAF
Port        Apphost HW capable
-------------------------------------------------------------------------------------
SS-2027                 00xx.abXX.bXXX       Up                        8443
          Yes

SS-2005         Enable 10xx/eaXX/100  CP2XXXX              USB to UART Bridge
 C
Vaxx-2006       Enable 10xx/eaXX/100  CP2XXXX              USB to UART Bridge
 C
```

86 EDCA Parameters

Topics:

- EDCA parameters

EDCA parameters

Introduces EDCA parameters and their role in prioritizing wireless traffic, detailing how to customize channel access for QoS using controller GUI or CLI interfaces.

An Enhanced Distributed Channel Access (EDCA) parameter is a wireless channel access configuration that

- assigns preferential access to voice, video, and other quality of service (QoS) traffic
- differentiates wireless traffic priority through distinct parameter settings, and
- enables customization of wireless performance using controller GUI or CLI interfaces.

Configure EDCA parameters (GUI)

Configure EDCA Parameters using GUI.

Set global EDCA parameters to optimize channel access for voice, video, and quality-of-service traffic on your wireless networks using GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Parameters**. On this window, you can configure global parameters for 802.11a/n/ac (5 GHz) and 802.11b/g/n (2.4 GHz) radios.

   Note

   You cannot configure or modify parameters, if the radio network is enabled. Disable the network status in the **Configuration** > **Radio Configurations** > **Network** window before proceeding. To apply the EDCA settings to the WLANs, disable and then re-enable the WLANs.

2. In the **EDCA Parameters** section, select an EDCA profile from the **EDCA Profile** drop-down list. Enhanced Distributed Channel Access (EDCA) parameters provide preferential wireless channel access for voice, video, and other QoS traffic.
3. For 802.11a/n/ac (5 GHZ) radios, in the (DFS 802.11h) section, enter the local power constraint. You cannot configure power constraint if the DTPC Support check box on the **Configure** > **Radio Configurations** > **Network** page is checked. The valid range is 0 dBm to 30 dBm.
4. Check the **Channel Switch Announcement Mode** check box, if you want the AP to announce when it is switching to a new channel and the new channel number. The default value is disabled.
5. Check the **Smart DFS** check box to enable Dynamic Frequency Selection (DFS) and avoid radar signal interference.
6. Click **Apply**.

Configure EDCA parameters (CLI)

Configure EDCA parameters using commands.

Set EDCA parameters on a wireless controller to optimize Quality of Service (QoS) for different traffic profiles and improve network performance using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable the radio network.

   Example

   ```
   Device(config)# ap dot11 {5ghz | 24ghz | 6ghz} shutdown
   ```

3. Enable specific EDCA parameters for the 802.11a, 802.11b/g, or 802.11 6-GHz network.

   Example

   ```
   Device(config)# ap dot11 {5ghz | 24ghz | 6ghz} edca-parameters
   {client-load-based | custom-voice | fastlane | optimized-video-voice |
   optimized-voice | svp-voice | wmm-default}
   ```

   Note

   The **custom-voice** option is not supported for Cisco Catalyst 9800 Series Wireless Controller .

   - **client-load-based**: Enables client load based EDCA configuration.
   - **custom-voice**: Enables custom voice parameters for the 802.11a or 802.11b/g network.
   - **fastlane**: Enables the fastlane parameters for the 802.11a or 802.11b/g network.
   - **optimized-video-voice**: Enables EDCA voice-optimized and video-optimized parameters for the 802.11a or 802.11b/g network. Choose this option when both voice and video services are deployed on your network.
   - **optimized-voice**: Enables non-SpectraLink voice-optimized profile parameters for the 802.11a or 802.11b/g network. Choose this option when voice services other than SpectraLink are deployed on your network.
   - **svp-voice**: Enables SpectraLink voice-priority parameters for the 802.11a or 802.11b/g network. Choose this option if SpectraLink phones are deployed on your network to improve the quality of calls.
   - **wmm-default**: Enables the Wi-Fi Multimedia (WMM) default parameters for the 802.11a or 802.11b/g network. This is the default option. Choose this option when voice or video services are not deployed on your network.

4. Enable the radio network and return to the privileged EXEC mode.

   Example

   ```
   Device(config)# no ap dot11 {5ghz | 24ghz | 6ghz} shutdown
   ```

   ```
   Device(config)# end
   ```

5. Display the current status of MAC optimization for voice.

Example

```
Device# show ap dot11 {5ghz | 24ghz | 6ghz} network
```

87 Adaptive Client Load-Based EDCA

Topics:

- Adaptive client load-based EDCA

Adaptive client load-based EDCA

Explains how adaptive client load-based EDCA mechanisms dynamically adjust wireless channel access parameters to improve performance in dense deployments.

An adaptive client load-based EDCA mechanism is a wireless medium access control feature that

- dynamically adjusts Enhanced Distributed Channel Access (EDCA) parameters for clients
- responds in real-time to the number of active clients and corresponding load, and
- significantly reduces radio collisions and performance degradation in dense deployments.

Feature Scenario

Run-time EDCA configuration based on active clients and load.

Feature history for adaptive client load-based EDCA

This table provides release and related information for the feature explained in this module.

This feature is available in all the releases subsequent to the one they were introduced in, unless noted otherwise.

Table 92: Feature History for Adaptive Client Load-Based EDCA

Feature Name	Release Information	Feature Description
Adaptive client load-based EDCA	Cisco IOS XE 17.5.1	This Adaptive Client Load-Based EDCA feature dynamically changes Enhanced Distributed Channel Access (EDCA) parameters of clients based on the active client and load that significantly reduce collisions.

Use case for adaptive client load-based EDCA

In a dense multiclient deployment scenario, a customer tested 40 iPads in a classroom or auditorium. He observed channel utilization was 60 to 70 percent.

- The overall AP throughput was lower due to air collision and RTS retries.
- After the adaptive client load-based EDCA feature was enabled, throughput increased by 15 to 20 percent, and collisions decreased by 30 to 40 percent.

Restrictions for adaptive client load-based EDCA

Adaptive client load-based EDCA restrictions.

You must disable the 802.11b network if you want to access the 802.11a network.

Configure adaptive client load-based EDCA (GUI)

Configure adaptive client load-based EDCA using GUI.

Adjust EDCA settings to optimize wireless radio performance based on client load using the GUI.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Parameters** to configure global parameters for 802.11a/n/ac (5-GHz) and 802.11b/g/n (2.4-GHz) radios.
2. In the **EDCA Parameters** section, select an **EDCA Profile** from the drop-down list.
3. Click the **Client Load Based Configuration** toggle button to enable or disable this feature. It is enabled by default.
4. In the **DFS (802.11h)** section for 802.11a/n/ac (5-GHz) radios, enter the local power constraint. You cannot configure power constraint if the **DPTC Support** check box in **Configuration** > **Radio Configurations** > **Network** is checked. The valid range for power constraint is 0 dBm to 30 dBm.
5. From the **Channel Switch Announcement Mode** drop-down list, select either the **Loud** or **Quiet** mode.
6. Click the **Smart DFS** toggle button to enable or disable this feature. It is enabled by default.
7. In the **11ax Parameters** section, use the corresponding toggle button to enable or disable the following features:
   - **Target Wakeup Time**
   - **Target Wakeup Time Broadcast**
   - **Multiple Bssid**
8. To enable BSS color for both the 5-GHz and 2.4-GHz radios, check the **BSS Color** check box.
9. Click **Apply**.

Configure adaptive client load-based EDCA (CLI)

Configure adaptive client load-based EDCA using commands.

Enable adaptive client load-based EDCA on 802.11 radios to optimize wireless traffic management based on client load using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable client load-based EDCA configuration for 802.11 radios.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz | 6ghz} edca-parameters
   client-load-based
   ```

   Use the **no** form of this command to disable the configuration.

> **Note**
>
> To enable the configuration on an 802.11a radio, you must disable the 802.11b network.

3. Return to the privileged EXEC mode.

Example

```
Device(config)# end
```

Verify adaptive client load-based EDCA configuration

Verify adaptive client load-based EDCA configuration.

To verify whether the adaptive client load-based EDCA feature is enabled on an 802.11a or an 802.11b radio, use this command:

```
Device# show ap dot11 24ghz network
Device# show ap dot11 5ghz network
EDCA profile type check                    : default-wmm
Client Load Based EDCA Config              : Enabled
```

To verify whether the adaptive client load-based EDCA feature is enabled on an 802.11 6-GHz radio, use this command:

```
Device# show ap dot11 6ghz network
.
.
.
EDCA profile type check                    : default-wmm
Client Load Based EDCA Config              : Enabled
```

To verify whether the adaptive client load-based EDCA feature is enabled on APs, use this command:

```
Device# show capwap client config
Client Load Based EDCA    : Enabled
```

To view the adaptive EDCA parameters running on the driver, use this command:

```
Device# show controllers dot11Radio 0/1
EDCA Config:
====================
L:Local C:Cell A:Adaptive EDCA params
AC Type CwMin CwMax Aifs Txop ACM
AC_BE L 4  6  3  0  0
AC_BK L 4  10 7  0  0
AC_VI L 3  4  1  94 0
AC_VO L 2  3  1  47 0
AC_BE C 4  10 3  0  0
AC_BK C 4  10 7  0  0
AC_VI C 3  4  2  94 0
```

```
AC_VO C 2 3 2 47 0
AC_BE A 4 10 7 0 0
AC_BK A 4 10 3 0 0
AC_VI A 3 4 2 94 0
AC_VO A 2 3 2 47 0
```

88 802.11 parameters and Band Selection

Topics:

- Band select

Band select

Explains how band select enables dual-band WLAN clients to connect to less congested 5-GHz channels and outlines how the controller regulates probe responses to achieve higher performance.

Band selection is a WLAN feature that

- enables dual-band client radios to connect to less congested 5-GHz APs
- improves overall network performance by reducing interference experienced on the controller, and
- uses probe response regulation to make 5-GHz channels more attractive to clients by delaying probe responses to clients on 2.4-GHz channels.

The 2.4-GHz band is often congested. Clients using the 2.4-GHz band often experience interference from Bluetooth devices, microwave ovens, cordless phones, and other access points. The 802.11b/g limit of three nonoverlapping channels also causes co-channel interference.

Band select works by regulating probe responses to clients and can be enabled on a per-WLAN basis. To view the band select table on an AP, run the **show dot11 band-select** command. It can also be viewed by running the **show cont d0/d1 | begin Lru** command.

You can enable both band selection and aggressive load balancing on the controller. They run independently and do not impact one another.

Band Select Algorithm

The band select algorithm affects clients that use 2.4-GHz band. When a client sends a probe request to an access point, the client's probe Active and Count values become one as seen in the band select table. The algorithm functions based on the following scenarios:

- Scenario 1: The client RSSI (as seen from the show cont d0/d1 | begin RSSIcommand output) is greater than both Mid RSSI and Acceptable Client RSSI.
  1. For dual-band clients, the access point does not send 2.4-GHz probe responses but sends 5-GHz probe responses for all 5-GHz probe requests.
  2. For single-band (2.4-GHz) clients, the access point sends 2.4-GHz probe responses only after the probe suppression cycle.
  3. When the client's probe count matches the configured probe cycle count, the algorithm waits for the Age Out Suppression time, marks the client probe's Active value as zero, and restarts.
- Scenario 2: Client RSSI (as seen from show cont d0/d1 | begin RSSI) lies between Mid-RSSI and Acceptable Client RSSI.
  1. All 2.4-GHz and 5-GHz probe requests are responded to without any restrictions.
  2. This scenario is similar to when band select is disabled.

     Note: The client RSSI value (from the sh cont d0 | begin RSSI command output) averages all client packets received. The Mid RSSI feature reports the instantaneous RSSI value of probe packets. Therefore, the client RSSI often appears weaker than the configured Mid RSSI value (by 7 dB). The 802.11b probes from the client are suppressed to push the client to associate with the 802.11a band.

802.11 bands

Configure the 802.11b/g/n (2.4 GHz) and 802.11a/n (5 GHz) on the controller to meet your country's regulatory requirements. By default, both 802.11b/g/n and 802.11a/n are enabled.

- 802.11n Parameters
- 802.11h Parameters

802.11n Parameters

This section provides instructions for managing 802.11n APs on your network. The 802.11n devices support the 2.4 and 5-GHz bands and offer high throughput data rates.

The 802.11n high throughput rates are available on all the 802.11n APs for the WLANs using WMM with no Layer 2 encryption or with WPA2/AES encryption enabled.

> **Note**
>
> If you want to disable MCS rates for 802.11n, 802.11ac, or 802.11ax, make sure at least one MCS rate remains enabled. To use only legacy 802.11a/b/g rates on your APs, first disable 802.11ax and 802.11ac on the controller for the specific band, then disable 802.11n. When you disable 802.11n globally on the controller, it affects all APs, even those mapped to a Custom RF Profile.

802.11h Parameters

802.11h informs client devices about channel changes and can limit the transmit power for those devices.

Restrictions for band selection, 802.11 bands, and parameters

Band Selection, 802.11 bands and parameters restrictions.

- Band selection-enabled WLANs do not support time-sensitive applications, such as voice and video, because roaming delays impact performance.
- Band selection is supported only on Cisco Wave 2 and 802.11ax APs.

  For more specific APs, see https://www.cisco.com/c/en/us/td/docs/wireless/access_point/feature-matrix/ap-feature-matrix.html .
- Band selection works only when your AP is connected to a controller. If you use a FlexConnect AP without a controller connection, it does not perform band selection after a reboot.
- Dual-band clients are directed from the 2.4-GHz radio to the 5-GHz radio of the same AP, but only when both radios are operational.
- To enable or disable band selection and client load balancing, configure these features for a specific WLAN. These settings are enabled globally by default, and you cannot change them globally through the controller GUI or CLI.

Configure band selection (GUI)

Configure band selection using GUI.

Before you begin

Ensure that you have configured an AP Join profile prior to configuring the primary and backup controllers.

Optimize wireless client performance by controlling band selection settings on the controller using GUI.

Procedure

1. Choose **Configuration** > **Wireless Advanced** > **Band Select**.
2. In the **Cycle Count** field, enter a value between one and 10. The cycle count sets the number of suppression cycles for a new client. The default cycle count is two.
3. In the **Cycle Threshold (milliseconds)** field, enter a value between one and 1000 milliseconds for the scan cycle period threshold. This setting determines the time threshold during which new probe requests from a client come from a new scanning cycle. The default cycle threshold is 200 milliseconds.
4. In the **Age Out Suppression (seconds)** field, enter a value between 10 and 200 seconds. Age-out suppression sets the expiration time for pruning previously known 802.11b/g/n clients. The default value is 20 seconds. After this time elapses, clients become new and are subject to probe response suppression.
5. In the **Age Out Dual Band (seconds)** field, enter a value between 10 and 300 seconds. The age-out period sets the expiration time for pruning previously known dual-band clients. The default value is 50 seconds. After this time elapses, clients become new and are subject to probe response suppression.
6. In the Client RSSI (dbm) field, enter a value between -90 to -20. This is the average of the client packets received.
7. In the Client Mid RSSI (dbm) field, enter a value between -90 to -20. This is the instantaneous RSSI value of the probe packets.
8. On the **AP Join Profile** page, click the AP Join Profile name.
9. Click **Apply**.

Configure band selection (CLI)

Configure band selection using commands.

Enable and fine-tune band selection parameters for wireless clients to optimize network performance using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Set the probe cycle count for band select.

   Example

   ```
   Device(config)# wireless client band-select cycle-count 3
   ```

   The valid range is between one and 10.

3. Set the time threshold for a new scanning cycle period.

   Example

   ```
   Device(config)# wireless client band-select cycle-threshold 5000
   ```

   The valid range is between one and 1000.

4. Set the suppression expire to the band select.

Example

```
Device(config)# wireless client band-select expire suppression 100
```

The valid range is between 10 and 200.

5. Set the dual band expire.

Example

```
Device(config)# wireless client band-select expire dual-band 100
```

The valid range is between 10 and 300.

6. Set the client RSSI threshold.

Example

```
Device(config)# wireless client band-select client-rssi 40
```

The valid range is between 20 and 90.

7. Configure band selection on specific WLANs.

Example

```
Device(config)# wlan wlan1 25 ssid12
```

```
Device(config-wlan)# band-select
```

The valid range is between one and 512. You can specify a value for the *SSID_network_name* parameter using up to 32 alphanumeric characters.

Configure the 802.11 bands (GUI)

Configure the 802.11 bands using GUI.

Modify wireless radio settings to optimize network performance for 2.4 GHz and 5 GHz bands using commands.

Procedure

1. Choose **Configuration** > **Radio Configurations** > **Network**.
2. Click on either **5 GHz Band** or **2.4 GHz Band**. Uncheck the **Network Status** check box to disable the network. This allows configuration of the network parameters.
3. In the **Beacon Interval** field, enter the rate at which the SSID is broadcast by the APs, from 100 to 600 milliseconds. The default is 100 milliseconds. For 802.11b/g/n (2.4-GHz) radios, to enable short preamble on the radio, check the **Short Preamble** check box. A short preamble improves throughput performance.
4. In the **Fragmentation Threshold (in bytes)** field, enter a value between 256 to 2346 bytes. Packets larger than the size you specify here will be fragmented.
5. Check the **DTPC Support** check box to advertise the transmit power level of the radio in the beacons and the probe responses. Client devices using dynamic transmit power control (DTPC) receive channel and power level information from APs. They then adjust their settings automatically. For example, a client device used primarily in Japan could rely on DTPC to adjust its channel and power settings automatically. When it travels to Italy and joins a network there,

the settings are updated as needed. If the **DTPC Support** check box is checked, you cannot configure a power constraint value on your 802.11a/n/ac (5-GHz) radio network. Click **Apply**.

6. In the **CCX Location Measurement** section, check the **Mode** check box to globally enable CCX radio management for the network. Once enabled, APs connected to this device issue broadcast radio measurement requests to clients running CCX v2 or later releases.
7. In the **Interval** field, enter a value to specify how often the APs must issue broadcast radio measurement requests. Click **Apply**.
8. In the **Data Rates** section, choose a value to specify the rates at which data can be transmitted between the AP and the client:
   - Mandatory: Clients must support this data rate to associate with an AP on the controllerembedded wireless controller.
   - Supported: Any associated client supporting this data rate may communicate with the AP using that rate.
   - Disabled: Clients specify the data rates used for communication.
9. Click **Apply** and save the configuration.

Configure the 802.11 bands (CLI)

Configure the 802.11 bands using commands.

Configure the various 802.11 wireless bands and essential parameters using commands.

Follow the procedure given below to configure 802.11 bands and parameters:

Procedure

1. Disable the 802.11a and 802.11b bands.

   Example

   ```
   Device(config)# ap dot11 5ghz shutdown
   ```

   ```
   Device(config)# ap dot11 24ghz shutdown
   ```

   Note

   You must disable the 802.11a band before configuring the 802.11a network parameters.

   You must disable the 802.11b band before configuring the 802.11b network parameters.

2. Disable the 802.11 6-GHz band.

   Example

   ```
   Device(config)# ap dot11 6ghz shutdown
   ```

> **Note**
>
> You must disable the 802.11 6-GHz band before configuring the 802.11 6-GHz network parameters.

3. Specify the rate at which the SSID is broadcast by the corresponding AP and the size at which packets are fragmented.

   Example

   ```
   Device(config)# ap dot11 {5ghz | 24ghz | 6ghz} beaconperiod 500
   ```

   ```
   Device(config)# ap dot11 {5ghz | 24ghz | 6ghz} fragmentation 300
   ```

   The beacon interval is measured in time units (TUs). One TU is 1024 microseconds. You can configure the AP to send a beacon every 20 to 1000 milliseconds.

   The threshold is a value between 256 and 2346 bytes (inclusive). Specify a low number for areas where communication is poor or where there is a great deal of radio interference.

4. Enable APs to advertise their channels and transmit the power levels in beacons and probe responses.

   Example

   ```
   Device(config)# ap dot11 {5ghz | 24ghz | 6ghz} dtpc
   ```

   ```
   Device(config)# no ap dot11 {5ghz | 24ghz | 6ghz} dtpc
   ```

   The default value is enabled. Client devices using dynamic transmit power control (DTPC) receive the channel-level and power-level information from the APs and adjust their settings automatically. For example, a client device used primarily in Japan can rely on DTPC to adjust its channel and power settings automatically when it travels to Italy and joins a network there.

   The **no** form of the command disables the DTPC setting.

5. Specify the maximum allowed number of clients that can be configured.

   Example

   ```
   Device(config)# wireless client association limit number 50 interval
   milliseconds 1000
   ```

   You can configure the maximum number of association requests on a single access point slot at a given interval. The range of association limit that you can configure is from one to 100.

   The association request limit interval is measured between 100 to 10000 milliseconds.

6. Specify the rate at which data can be transmitted between the controllerembedded wireless controller and the client.

   Example

   ```
   Device(config)# ap dot11 {5ghz | 24ghz} rate 36 {disable | mandatory |
   supported}
   ```

   - **disable**: Defines that the clients specify the data rates used for communication.

- **mandatory**: Defines that the clients support this data rate in order to associate to an AP on the controllerembedded wireless controller.
- **supported**: Any associated clients that support this data rate can communicate with the AP using that rate. However, the clients are not required to use this rate in order to associate.
- *rate*: Specifies the rate at which data is transmitted. For the 802.11a and 802.11b bands, the data is transmitted at the rate of one, two, 5.5, six, nine, 11, 12, 18, 24, 36, 48, or 54 Mbps.

7. Enable the 802.11a and 802.11b bands.

   Example

   ```
   Device(config)# no ap dot11 5ghz shutdown
   ```

   ```
   Device(config)# no ap dot11 24ghz shutdown
   ```

   Note

   The default value is enabled.

8. Enable the 802.11 6-GHz band.

   Example

   ```
   Device(config)# no ap dot11 6ghz shutdown
   ```

   Note

   The default value is enabled.

9. Enable or disable 802.11g network support. Then return to privileged EXEC mode.

   Example

   ```
   Device(config)# ap dot11 24ghz dot11g
   ```

   ```
   Device(config)# end
   ```

   The default value is enabled. You can use this command only if the 802.11b band is enabled. If you disable this feature, the 802.11b band is enabled without 802.11g support.

Configure a band-select RF profile (GUI)

Configure a band-select RF profile using GUI.

Configure specific parameters in a band-select RF profile to optimize client band steering behavior on your wireless network.

Procedure

1. Choose **Configuration** > **Wireless** > **Advanced**.
2. In the **Band Select** tab, enter a value between one and 10 in the **Cycle Count** field. The cycle count determines how many suppression cycles are applied to each new client. The default cycle count is two.
3. In the **Cycle Threshold** field, enter a value between one and 1000 milliseconds to define the scan cycle period threshold. his setting specifies the time period in which probe requests from a client are recognized as part of a new scanning cycle. The default cycle threshold value is 200 milliseconds.
4. In the **Age Out Suppression** field, enter a value between 10 and 200 seconds. Age-out suppression establishes the expiration time for removing records of previously known 802.11b/g/n clients. The default value is 20 seconds. After the expiration time, clients are treated as new and become subject to probe response suppression.
5. In the **Age Out Dual Band** field, enter a value between 10 and 300 seconds. The age-out period establishes the expiration time for removing records of previously known dual-band clients. The default value is 50 seconds. After the expiration period, clients are considered new and are subject to probe response suppression.
6. In the **Client RSSI** field, enter a value between -90 dBm and -20 dBm. This value sets the minimum RSSI required for a client to respond to a probe.
7. In the **Client Mid RSSI** field, enter a value between -20 dBm and -90 dBm. This parameter defines the mid-RSSI value, which can be used to toggle 2.4 GHz probe suppression depending on the RSSI.
8. Click **Apply**.

Configure a band-select RF profile (CLI)

Configure a band-select RF profile using commands.

Customize how band selection operates on 2.4 GHz radios by defining parameters in an RF profile using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the RF profile name and enter the RF profile configuration mode.

   Example

   ```
   Device(config)# ap dot11 24ghz rf-profile test1
   ```

3. Set the band-select client threshold.

   Example

   ```
   Device(config-rf-profile)# band-select client {mid-rssi | rssi} -90
   ```

4. Set the band-select cycle parameters.

Example

```
Device(config-rf-profile)# band-select cycle {count | threshold} 10
```

5. Configure the RF profile's band-select expiry time.

Example

```
Device(config-rf-profile)# band-select expire {dual-band | suppression} 100
```

6. Enable the RF profile's band-select probe response.

Example

```
Device(config-rf-profile)# band-select probe-response
```

Configure 802.11n parameters (GUI)

Configure 802.11n parameters using GUI.

Apply custom 802.11n wireless settings to an RF profile in the device management GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **RF**.
2. Click **Add** to view the **Add RF Profile** window.
3. In the **802.11** tab, complete these steps:
   a) Choose the required operational rates.
   b) Select the required **802.11n MCS Rates** by checking the corresponding check boxes.
4. Click **Save & Apply to Device**.

Configure 802.11n parameters (CLI)

Configure 802.11n parameters using commands.

Configure and optimize 802.11n settings on a wireless AP using commands.

Procedure

1. Enable 802.11n support on the network.

Example

```
Device(config)# ap dot11 {5ghz | 24ghz} dot11n
```

The **no** form of this command disables the 802.11n support on the network.

2. Specify the modulation and coding scheme (MCS) rates for data transmission between the access point and the client.

Example

```
Device(config)# ap dot11 {5ghz | 24ghz} dot11n mcs tx 20
```

rtu: The valid range is zero to 23.

The **no** form of this command disables the MCS rates that are configured.

3. Enable WMM on the WLAN and uses the 802.11n data rates that you configured.

Example

```
Device(config)# wlan wlan1 25 ssid12
```

```
Device(config-wlan)# wmm require
```

The **require** keyword requires client devices to use WMM. Devices that do not support WMM cannot join the WLAN.

4. Disable the network.

Example

```
Device(config)# ap dot11 {5ghz | 24ghz} shutdown
```

5. Specify the aggregation method used for 802.11n packets.

Example

```
Device(config)# {ap | no ap} dot11 {5ghz | 24ghz} dot11n a-mpdu tx priority
{all | 0-7}
```

Aggregation is the process of grouping packet data frames together, rather than transmitting them separately. Two aggregation methods are available: Aggregated MAC Protocol Data Unit (A-MPDU) and Aggregated MAC Service Data Unit (A-MSDU). Both A-MPDU and A-MSDU are performed in the software.

You can specify the aggregation method for various types of traffic from the access point to the clients.

The list defines the priority levels (zero-7) assigned per traffic type.

- Zero–Best effort
- One–Background
- Two–Spare
- Three–Excellent effort
- Four–Controlled load
- Five–Video, less than 100-ms latency and jitter
- Six–Voice, less than 100-ms latency and jitter
- Seven–Network control

You can configure each priority level independently or use all the parameters to configure every priority level simultaneously. You can configure priority levels so that the traffic uses either A-MPDU transmission or A-MSDU transmission.

- When you use the **ap** command with other options, traffic at that priority level uses A-MPDU transmission.

- When you use the **no ap** command along with the other options, the traffic associated with that priority level uses A-MSDU transmission.

  Configure the priority levels to match the aggregation method used by the clients. By default, both A-MPDU and A-MSDU are enabled for priority levels zero to five; all other levels are disabled.

> **Note**
>
> Tracking the TX retries value by internal MSDUs instead of the whole PPDU in Cisco IOS XE 17.12 and later versions provides a more accurate count for the AP's retries. This adjustment has led to a notable increase in retry count values because multiple MSDUs are contained within a single PPDU. This change is intentional and will be implemented in all future versions of Cisco IOS XE.

6. Re-enable the network.

   Example

```
Device(config)# no ap dot11 {5ghz | 24ghz} shutdown
```

7. Configure the guard interval for the network.

   Example

```
Device(config)# ap dot11 {5ghz | 24ghz} dot11n guard-interval {any | long}
```

8. Configure the Reduced Interframe Space (RIFS) for the network.

   Example

```
Device(config)# ap dot11 {5ghz | 24ghz} dot11n rifs rx
```

9. Return to privileged EXEC mode. Alternatively, press **Ctrl-Z** to exit global configuration mode.

   Example

```
Device(config)# end
```

Configure 802.11h parameters (CLI)

Configure 802.11h parameters using commands.

Configure 802.11h parameters on a wireless AP using commands to manage compliance, interference, and transmit power settings.

Procedure

1. Disable the 802.11 network.

Example

```
Device(config)# ap dot11 5ghz shutdown
```

2. Disable the 802.11 6-GHz network.

Example

```
Device(config)# ap dot11 6ghz shutdown
```

3. Enable or disable the AP to announce when it is switching to a new channel.

Example

```
Device(config)# {ap | no ap} dot11 5ghz channelswitch mode 0
```

switch_mode: Enter zero or one to specify whether transmissions are restricted until the actual channel switch (***zero***) or are not restricted (***one***). The default value is disabled.

4. Enable or disable the AP to announce when it is switching to a new channel in quiet mode.

Example

```
Device(config)# ap dot11 5ghz channelswitch quiet
```

```
Device(config)# no ap dot11 6ghz channelswitch quiet
```

5. Configure the 802.11h power constraint value in dB.

Example

```
Device(config)# ap dot11 5ghz power-constraint 200
```

The valid range is from zero to 255. The default value is three.

6. Configure the 802.11 6-GHz power constraint value in dB.

Example

```
Device(config)# ap dot11 5ghz power-constraint 200
```

The valid range is from zero to 30. The default value is three.

7. Re-enable the 802.11a network.

Example

```
Device(config)# no ap dot11 5ghz shutdown
```

8. Re-enable the 802.11 6-GHz network.

Example

```
Device(config)# no ap dot11 6ghz shutdown
```

9. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

Verify configuration settings using band selection and 802.11 bands commands

Verify configuration settings using band selection and 802.11 bands commands.

Use these commands to verify band selection, 802.11 bands, and parameters on the device.

Table 93: Monitoring configuration settings using band selection and 802.11 band commands

Command	Purpose
show ap dot11 5ghz network	Displays 802.11a band network parameters, 802.11a operational rates, 802.11n MCS settings, and 802.11n status information.
show ap dot11 24ghz network	Displays 802.11b band network parameters, 802.11b/g operational rates, 802.11n MCS settings, and 802.11n status information.
show ap dot11 6ghz network	Displays 802.116-GHz band network parameters, 802.11b/g operational rates, 802.11n MCS settings, and 802.11n status information.
show wireless dot11h	Displays 802.11h configuration parameters.
show wireless band-select	Displays band-select configuration settings.

Example: view the configuration settings for the 6-GHz band

View the 6-GHz band example configuration settings.

```
Device# show ap dot11 6ghz network

Examples: band selection configuration

Band selection configuration examples.

This example shows how to set the probe cycle count and time threshold for a new scanning cycle period for band select:

```
Device# configure terminal
(config)# wireless client band-select cycle-count 3
(config)# wireless client band-select cycle-threshold 5000
(config)# end
```

This example shows how to set the suppression expiry time to the band select:

```
Device# configure terminal
(config)# wireless client band-select expire suppression 100
(config)# end
```

This example shows how to set the dual-band expiry time for the band select:

```
Device# configure terminal
(config)# wireless client band-select expire dual-band 100
(config)# end
```

This example shows how to set the client RSSI threshold for the band select:

```
Device# configure terminal
(config)# wireless client band-select client-rssi 40
(config)# end
```

This example shows how to configure band selection on specific WLANs:

```
Device# configure terminal
(config)# wlan wlan1 25 ssid12
(config-wlan)# band-select
(config)# end
```

Examples: 802.11 bands configuration

802.11 bands configuration examples.

This example shows how to configure 802.11 bands using beacon interval, fragmentation, and dynamic transmit power control:

```
Device# configure terminal
config)# ap dot11 5ghz shutdown
(config)# ap dot11 24ghz shutdown
(config)# ap dot11 5ghz beaconperiod 500
(config)# ap dot11 5ghz fragmentation 300
(config)# ap dot11 5ghz dtpc
(config)# wireless client association limit 50 interval 1000
(config)# ap dot11 5ghz rate 36 mandatory
(config)# no ap dot11 5ghz shutdown
(config)# no ap dot11 24ghz shutdown
(config)# ap dot11 24ghz dot11g
(config)# end
```

Examples: 802.11n configuration

802.11n configuration examples.

This example shows how to configure 802.11n parameters for 5-GHz band using aggregation method:

```
Device# configure terminal
(config)# ap dot11 5ghz dot11n
(config)# ap dot11 5ghz dot11n mcs tx 20
(config)# wlan wlan1 25 ssid12
(config-wlan)# wmm require
(config-wlan)# exit
(config)# ap dot11 5ghz shutdown
(config)# ap dot11 5ghz dot11n a-mpdu tx priority all
(config)# no ap dot11 5ghz shutdown
(config)# exit
```

This example shows how to configure the guard interval for 5-GHz band:

```
Device# configure terminal
(config)# ap dot11 5ghz dot11n
(config)# ap dot11 5ghz dot11n mcs tx 20
(config)# wlan wlan1 25 ssid12
(config-wlan)# wmm require
(config-wlan)# exit
(config)# no ap dot11 5ghz shutdown
(config)# ap dot11 5ghz dot11n guard-interval long
(config)# end
```

This example shows how to configure the RIFS for 5-GHz band:

```
Device# configure terminal
(config)# ap dot11 5ghz dot11n
(config)# ap dot11 5ghz dot11n mcs tx 20
(config)# wlan wlan1 25 ssid12
(config-wlan)# wmm require
(config-wlan)# exit
(config)# ap dot11 5ghz shutdown
(config)# ap dot11 5ghz dot11n rifs rx
(config)# end
```

Examples: 802.11h configuration

802.11h configuration examples.

This example shows how to configure the AP to announce when it is switching to a new channel using restriction transmission:

```
Device# configure terminal
(config)# ap dot11 5ghz shutdown
(config)# ap dot11 5ghz channelswitch mode 0
(config)# no ap dot11 5ghz shutdown
(config)# end
```

This example shows how to configure the 802.11h power constraint for 5-GHz band:

```
Device# configure terminal
(config)# ap dot11 5ghz shutdown
(config)# ap dot11 5ghz power-constraint 200
(config)# no ap dot11 5ghz shutdown
(config)# end
```

89 NBAR Protocol Discovery

Topics:

- NBAR protocol discovery

NBAR protocol discovery

Explains NBAR Protocol Discovery, detailing supported protocols, configuration steps for traffic monitoring through GUI and CLI, and methods for verifying protocol statistics to improve network traffic management and application visibility.

NBAR protocol discovery is a network traffic analysis feature that

- identifies and classifies application protocols passing through a network interface from Layer 4 through Layer 7
- collects protocol-specific traffic statistics for supported applications, and
- enables network administrators to monitor application performance and usage trends.

Network Based Application Recognition (NBAR) identifies which protocols and applications are currently running on the network. Use Protocol Discovery to find protocol traffic supported by NBAR and view related statistics.

NBAR also supports Cisco Application Visibility and Control (AVC). With AVC, NBAR helps you improve application performance with enhanced QoS and policing. It gives you more detailed visibility into your network.

Restrictions of NBAR

NBAR cannot accurately classify traffic when SaaS applications use end-to-end encryption, QUIC, or DoH, because encryption blocks traffic analysis.

- In these cases, encrypted traffic (including DoH and QUIC without SNI) limits NBAR, so it may not report the correct Protocol ID. As a result, you might experience issues with traffic classification.

Configure NBAR protocol discovery (CLI)

Configure NBAR protocol discovery using commands.

Follow this procedure to enable protocol discovery.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy nbar-proto-policy
   ```

3. Configure the wireless policy profile for central switching.

   Example

   ```
   Device(config-wireless-policy)# central switching
   ```

> **Note**
>
> NBAR protocol discovery is supported in local mode (central switching) and in FlexConnect (central switching) mode.

4. Enable application recognition on the wireless policy profile by activating the NBAR2 engine.

Example

```
Device(config-wireless-policy)# ip nbar protocol-discovery
```

Verify protocol discovery statistics

Verify protocol discovery statistics.

To view protocol discovery statistics, use the command:

```
Device# show ip nbar protocol-discovery wlan wlan-profile-name
wlan_profile_name (iif_id 0xF0400002)

Last clearing of "show ip nbar protocol-discovery" counters 00:07:12

Input                    Output

                                  204                      236
                                  0                        0
                                  0                        0
Total                         27                       4
                                 5543                     960
                                 0                        0
                                 2000                     0
```

To clear protocol discovery statistics, use the command:

```
Device# clear ip nbar protocol-discovery wlan wlan-profile-name
```

90 Conditional Debug, Radioactive Tracing, and Packet Tracing

Topics:

- Conditional debugging
- Packet tracing
- Wireless client debug bundle

Conditional debugging

Introduces conditional debugging, enabling selective activation of debug and logging outputs based on user-defined conditions such as interface, IP address, or MAC address to optimize resource usage and performance in large-scale networks.

A conditional debugging is a diagnostic feature that

- enables selective activation of debugging and logging for specific features based on conditions you define
- allows you to define custom conditions such as interface, IP address, or MAC address to narrow debug scope, and
- helps reduce system resource usage and performance impact in large, complex networks.

Use this feature in systems with many supported features.

Conditional debug allows granular debugging in networks operating at large scale with many features. It allows you to observe detailed debug output for specific instances within the system.

In contrast, the general debug command produces output without filtering feature objects being processed. The general debug command uses significant system resources and affects performance.

Radioactive tracing

Introduces radioactive tracing for enhanced diagnostic logging across system components, outlines conditional debugging techniques for FHS and mesh networking, and details relevant commands, supported components, and important considerations such as certificate validity and MAC address configuration.

A radioactive tracing is a diagnostic tracing mechanism that

- stitches together a chain of execution for operations of interest across the system, at an increased verbosity level
- enables conditional printing of detailed debug information across threads, processes and function calls, and
- troubleshoot system features, especially First-Hop Security (FHS) and mesh networking functions.

Note

- For more information on First Hop Security features, see **System Management** > **Wireless Multicast** > **Information About Wireless Multicast** > **Information About IPv6 Snooping**.
- The radioactive tracing filter does not work, if the certificate is not valid.
- To debug mesh features effectively, add both Ethernet and Radio MAC addresses as conditional MACs for RA tracing when you collect logs.
- To enable debugging for wireless IPs, use the **debug platform condition feature wireless ip** *ip-address* command.

Table 94: Components Supporting Radio Active Tracing

Components	Details
SISF or FHS	The first-hop security features, includes IPv6 Address Glean and IPv6 Device Tracking. For more information, see *Information About IPv6 Snooping*.

Components	Details
LISP	Locator or ID Separation Protocol.

Feature history for conditional debug and radioactive tracing

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 95: Feature history for conditional debug and radioactive tracing

Feature Name	Release Information	Feature Description
Conditional debug and radioactive tracing	Cisco IOS XE 17.11.1	Conditional debugging is a diagnostic feature that selectively activates debugging and logging based on defined conditions to optimize resource usage and performance in complex networks, while radioactive tracing is a diagnostic mechanism that stitches together execution chains with increased verbosity, enabling conditional detailed debug information across system components for troubleshooting specific features.

Conditional debugging and radioactive tracing

Introduces conditional debugging and radioactive tracing, detailing how to target specific execution contexts, trace code paths across multiple control flows, and use a unified debug CLI, as well as how to clear applied debug conditions.

A conditional debugging and radioactive tracing feature is a diagnostic mechanism that

- combines the precision of conditional debugging to target specific execution contexts
- leverages radioactive tracing to follow code paths across multiple control flows, and
- enables use of a single debug CLI to debug all execution contexts related to the condition.

> **Note**
>
> Use the **clear platform condition all** command to remove the debug conditions applied to the platform.

Location of tracefiles

Tracefile location details.

Tracefiles are generated for each process and saved in either the `/tmp/rp/trace` or `/tmp/fp/trace` directory. Each trace log is written to a file of 1 MB. The directory can hold up to a maximum of 25 such files for a given process.

When a tracefile in the `/tmp` directory reaches its 1MB limit or the configured size, it is rotated out to an archive location in the `/crashinfo` partition under the `tracelogs` directory.

- Process-name_pmanlog_Process-ID_running-counter.timestamp.bin.gz

  Example: wncmgrd_R0-0.27958_1.20180902081532.bin.gz

The `/tmp` directory holds only a single tracefile for a given process. Once a tracefile reaches its size limit, the system moves it to `/crashinfo/tracelogs`. The archive directory stores up to 25 files and replaces the oldest file with each new file from `/tmp`. File size varies by process. Some processes use larger files that can reach 10 MB.

- The number of files stored in the `tracelogs` directory also depends on the process. For example, the WNCD process may use a limit of up to 400 files per instance, depending on the platform.
- You can verify these logs (per-process) using the **show platform software trace message** *process_name* **chassis active R0** command.

Configure conditional debugging (GUI)

Configure conditional debugging using GUI.

Enable targeted troubleshooting by configuring conditional debugging through the GUI, allowing you to capture and analyze logs for specific MAC or IP addresses.

Procedure

1. Choose **Troubleshooting** > **Radioactive Trace**. Click **Add**.
2. Enter the **MAC/IP Address**. The MAC address can be either in *xx:xx:xx:xx:xx:xx* , *xx-xx-xx-xx-xx-xx* , or *xxxx.xxxx.xxxx* format.
3. Click **Apply to Device**.
4. Click **Start** to start or **Stop** to stop the conditional debug.
5. Click **Generate** to create a radioactive trace log.
6. Click the radio button to set the time interval.
7. Click the **Download Logs** icon that is displayed next to the trace file name, to download the logs to your local folder.
8. Click the **View Logs** icon that is displayed next to the trace file name, to view the log files on the GUI page.
9. Click **Load More** to view more lines of the log file. Click **Apply to Device**.

Configure conditional debugging (CLI)

Configure conditional debugging using commands.

Enable targeted troubleshooting for wireless features by filtering debug output to specific APs, clients, or IP addresses using commands.

Procedure

1. Configure conditional debugging for a feature using the specified MAC address.

Example

```
Device# debug platform condition feature wireless mac b838.61a1.5433
```

> **Note**
>
> This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.

2. Start conditional debugging.

Example

```
Device# debug platform condition start
```

This starts radioactive tracing if there is a match on one of the conditions above.

> **Note**
>
> This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.

3. Display the current conditions set.

Example

```
Device# show platform condition
```

```
Device# show debugging
```

4. Stop conditional debugging.

Example

```
Device# debug platform condition stop
```

This will stop radioactive tracing.

> **Note**
>
> This is supported with AP or client MAC/IP and also on CMX IP address and mobility peer IP.

5. Display the logs from the latest wireless profile.

Example

```
Device# show logging profile wireless [ counter start last {20 minutes} |
filter mac {mac-address}  to-file bootflash:logs.txt]
```

> **Note**
>
> You can use either the **show logging profile wireless** command or **show logging process** command to collect the logs.

6. Display the logs collection specific to the process.

   Example

   ```
   Device# show logging process wncd to-file flash:wncd.txt
   ```

7. Clear all conditions.

   Example

   ```
   Device# clear platform condition all
   ```

What to do next

The command **request platform software trace filter-binary wireless** *mac-address* generates 3 flash files:

- collated_log_<.date..>
- mac_log <..date..>
- mac_database .. file

The *mac_log <..date..>* file is the most important because it contains messages related to the MAC address under investigation. The **show platform software trace filter-binary** command generates the same flash files and displays the mac_log on the screen.

Radioactive Tracing for L2 Multicast

L2 Multicast Radioactive Tracing details.

To identify a specific multicast receiver, specify the MAC address of the joiner or the receiver client, Group Multicast IP address and Snooping VLAN. Additionally, enable the trace level for the debug. The debug level will provide detailed traces and better visibility into the system.

debug platform condition feature multicast controlplane *igmp-mld-debug igmp-snooping level mld-snooping pim*

Recommended workflow for trace files

Trace files recommended workflow details.

The recommended workflow for trace files is listed below:

- To request the tracelogs for a specific time period, such as 1 day, use the command: Device# **show logging process wncd to-file flash:wncd.txt**.
- The system generates a text file of the tracelogs in the location /flash:
- Copy the file off the device so the tracelogs can be used to work offline. For more details on copying files, see section below.
- Delete the tracelog file (.txt) from the /flash: location to ensure enough space on the device for other operations.

Copy tracefiles off the box

Off the box copying tracefiles details.

This is an example of the tracefile:

```
Device# dir crashinfo:/tracelogs
Directory of crashinfo:/tracelogs/
50664 -rwx 760 Sep 22 2015 11:12:21 +00:00 plogd_F0-0.bin_0.gz
50603 -rwx 991 Sep 22 2015 11:12:08 +00:00
fed_pmanlog_F0-0.bin_0.9558.20150922111208.gz
50610 -rw- 11 Nov 2 2015 00:15:59 +00:00 timestamp
50611 -rwx 1443 Sep 22 2015 11:11:31 +00:00
auto_upgrade_client_sh_pmanlog_R0-.bin_0.3817.20150922111130.gz
50669 -rwx 589 Sep 30 2015 03:59:04 +00:00 cfgwr-8021_R0-0.bin_0.gz
50612 -rwx 1136 Sep 22 2015 11:11:46 +00:00
reflector_803_R0-0.bin_0.1312.20150922111116.gz
               50794 -rwx 4239 Nov 2 2015 00:04:32 +00:00
IOSRP_R0-0.bin_0.14239.20151101234827.gz
50615 -rwx 131072 Nov 2 2015 00:19:59 +00:00 linux_iosd_image_pmanlog_R0-0.bin_0
```

The trace files can be copied using one of the various options shown below:

```
Device# copy crashinfo:/tracelogs ?
  crashinfo: Copy to crashinfo: file system
  flash: Copy to flash: file system
  ftp: Copy to ftp: file system
  http: Copy to http: file system
  https: Copy to https: file system
  null: Copy to null: file system
  nvram: Copy to nvram: file system
  rcp: Copy to rcp: file system
  running-config Update (merge with) current system configuration
  scp: Copy to scp: file system
  startup-config Copy to startup configuration
  syslog: Copy to syslog: file system
  system: Copy to system: file system
  tftp: Copy to tftp: file system
  tmpsys: Copy to tmpsys: file system
```

The general syntax for copying onto a TFTP server is as follows:

```
Device# copy source: tftp:
Device# copy crashinfo:/tracelogs/IOSRP_R0-0.bin_0.14239.20151101234827.gz
tftp:
Address or name of remote host []? 2.2.2.2
Destination filename [IOSRP_R0-0.bin_0.14239.20151101234827.gz]?
```

> **Note**
>
> Clear the generated report and archive files from the switch to ensure that sufficient flash space remains available for tracelog and other uses.

Configuration examples for conditional debugging

Conditional debugging configuration examples.

This is an output example of the **show platform condition** command.

```
Device# show platform condition
Conditional Debug Global State: Stop
Conditions Direction
------------------------------------------------------------------------------------|--------
MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value
----------------------|----------------------|--------------------------------
```

This is an output example of the **show debug** command.

```
Device# show debug
IOSXE Conditional Debug Configs:
Conditional Debug Global State: Start
Conditions Direction
------------------------------------------------------------------------------------|--------
MAC Address 0024.D7C7.0054 N/A
Feature Condition Type Value
----------------------|----------------------|--------------------------------
Packet Infra debugs:
Ip Address Port
------------------------------------------------------|----------
```

Verify conditional debugging

Verify conditional debugging.

The table shown below lists the various commands that can be used to verify conditional debugging:

Command	Purpose
show platform condition	Displays the current conditions set.
show debug	Displays the current debug conditions set.
show platform software trace filter-binary	Displays logs merged from the latest tracefile.
request platform software trace filter-binary	Displays historical logs of merged tracefiles on the system.

Example: verify radioactive tracing log for SISF

Verify radioactive tracing log for SISF example.

This is an output example of the **show platform software trace message ios chassis active R0 | inc sisf** command.

```
Device# show platform software trace message ios chassis active R0 | inc sisf

Packet tracing

Introduces packet tracing for Cisco Catalyst 9800 Series Wireless Controller for Cloud, detailing how to enable and use conditional debugging, apply per-AP and per-Client tracing, and explaining limitations of filtering with MAC or IP headers in CAPWAP-encapsulated packets.

A packet tracing is a network diagnostic tool that

- tracks the flow and processing of individual data packets through a network device
- provides detailed per-packet information based on user-defined conditions for troubleshooting purposes, and
- helps identify network issues such as misconfiguration, capacity overload, and software bugs.

The packet tracing feature explains how to perform data plane packet tracing for Cisco Catalyst 9800 Series Wireless Controller for Cloud software.

To trace packets on the controller:

1. Enable conditional debugging on selected packets or traffic to trace.
2. Enable packet tracing (per-AP or per-Client).

> **Note**
>
> Use per-AP conditional debugging with a MAC address filter when the AP and controllers are in the same VLAN. If they are in different VLANs, per-AP packet tracing with a MAC address does not capture packets because the MAC address varies.

Limitation of Conditional Debugging Packet Tracing

The MAC or IP filter applies only to the outer Ethernet or IP header. If a packet is CAPWAP encapsulated, the MAC or IP filter does not affect the inner 802.11 MAC or IP header.

Configure conditional debugging packet tracing (CLI)

Configure conditional debugging packet tracing using commands.

Enable and manage in-depth packet tracing for troubleshooting and diagnostics while minimizing resource usage using commands.

Procedure

1. Enable the privileged **EXEC** mode.

   Example

   ```
   Device# enable
   ```

   Enter your password, if prompted.

2. Configure packet tracing to capture the last set of packets.

   Example

   ```
   Device# debug platform packet-trace packet 8192 circular fia-trace data-size
    2048
   ```

   packet-count: Here, the valid range is from 16 to 8192.

   data-size: Here, the valid range is from 2048 to 16384 bytes.

3. Configure packet tracing for a copy of packet data.

   Example

   ```
   Device# debug platform packet-trace copy packet both size 2048
   ```

   packet-size: Here, the valid range is from 16 to 2048 bytes.

4. Enable conditional debugging for an interface, MAC, or IP filter.

Example

Enable conditional debugging for TenGigabitEthernet 0/0/0 and match packets whose source and destination MAC is 192.0.2.1:

```
Device# debug platform condition interface {interface-name TenGigabitEthernet
 | cpp} 0/0/0 {mac | ipv4 | match} 192.0.2.1 {both | ingress | egress}
```

An interface refers to any physical port, port channel, internal vlan, SVI, or wireless client.

5. Start conditional debugging packet tracing.

Example

```
Device# debug platform condition start
```

6. Stop conditional debugging packet tracing.

Example

```
Device# debug platform condition stop
```

7. Redirect all traced packets to bootflash.

Example

```
Device# show platform hardware chassis active qfp feature packet-trace packet
 all | redirect bootflash:packet_trace.txt
```

Convert the packet_trace.txt to pcap and download the pcap files. You can do so using this link:

http://wwwin-dharton-dev.cisco.com/pactrac2pcap.html

Configure conditional debugging packet tracing per AP (CLI)

Configure conditional debugging packet tracing per AP.

Enable conditional debugging to trace CAPWAP packets for a specific AP by filtering with MAC or IP address using commands.

Procedure

1. Enable privileged **EXEC** mode.

Example

```
Device# enable
```

Enter your password, if prompted.

2. Enable conditional debugging with MAC filter.

Example

```
Device# debug platform condition interface {interface-name TenGigabitEthernet
 | cpp} 0/0/0 {mac 192.0.2.1 | access-list acl-name | ipv4 | match} {both |
ingress | egress}
```

Here, the CLI matches the packets whose source or destination MAC address is 192.0.2.1

3. Enable conditional debugging with inline MAC ACL.

Example

```
Device# debug platform condition interface TenGigabitEthernet 0/0/0 match mac
 { H.H.H. | any | host} 192.0.2.1 {both | ingress | egress}
```

4. Enable conditional debugging with IP filter.

Example

```
Device# debug platform condition interface TenGigabitEthernet 0/0/0 ipv4
{192.0.2.1 | access-list ip-acl-name| both | egress | ingress} {both | egress
 | ingress}
```

0/0/0: is the GigabitEthernet interface number. The valid range is from 1 to 32.

Configure conditional debugging packet tracing per client (GUI)

Configure conditional debugging packet tracing per client using GUI.

Enable targeted packet tracing for individual clients to facilitate in-depth troubleshooting and analysis using GUI.

Procedure

1. Choose **Troubleshooting** > **Radioactive Trace**.
2. Click **Add**.
3. In the Add MAC/IP Address window, enter the **MAC/IP Address**.
4. Click **Apply to Device**.

Configure conditional debugging packet tracing per client (CLI)

Configure conditional debugging packet tracing using commands.

Enable conditional debugging to trace packets for a specific wireless client, helping to diagnose network issues more efficiently using commands.

Procedure

1. Enable privileged **EXEC** mode.

Example

```
Device# enable
```

Enter your password, if prompted.

2. Enable conditional debugging for a wireless client interface.

Example

```
Device# debug platform condition interface {intf-name | cpp 0xa0000001} { mac
 | ipv4 | match [ipv4 | ipv6 | mac]} protocol icmp host 192.0.2.1 host
192.0.2.1 {both | ingress | egress}
```

cpp-handle-index: The valid range is from 1 to 4294967295.

Verify conditional debugging packet tracing configuration

Verify conditional debugging packet tracing configuration.

To view the summary of the traced packet, use this command:

```
Device# show platform packet-trace summary
```

To view a specific traced packet, use this command:

```
Device# show platform packet-trace packet <packet number>
```

To view the wireless client interface handle, use this command:

```
Device# show platform hardware chassis active qfp feature wireless wlclient
cpp-client mac-address client-mac details
Device# show platform hardware chassis active qfp feature wireless wlclient
cpp-client mac-address 8825.93b0.b51f details
Client Details for client cpp_if_handle: 0x34
Name : WLCLIENT-IF-0x00a0000001
Mac Addr : 8825.93b0.b51f
pal_if_handle : 0xa0000001
Mobility State : LOCAL
Multicast Action : FORWARD
Auth State : RUN
```

Wireless client debug bundle

Introduces the wireless client debug bundle feature, detailing how it streamlines troubleshooting by collating debug logs, packet captures, show command outputs, and AP logs into a single file, and highlighting its release history and usage considerations.

A wireless client debug bundle is a troubleshooting feature that

- collates client-specific debug logs, packet captures, and relevant show command outputs
- packages them into a single compressed tar file for easier analysis, and
- streamlines client issue investigation by reducing the need to run multiple commands.

In earlier releases, logs were collected through various individual steps and commands. Now, the output of **show** commands related to clients is collected in a tar file through a single **debug** command. From Cisco IOS XE Cupertino 17.11.1, client debug bundle collates AP logs along with the existing controller bundle.

> **Note**
>
> The client debug bundle is not supported on HA with Stateful Switch Over (SSO).

> **Note**
>
> When you enable the **all** command option on the AP console, the command activates debug logging for all clients. This action can result in an excessive amount of logs being printed to the console.

Feature history for wireless client debug bundle

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 96: Feature History for client debug bundle

Feature Name	Release Information	Feature Description
Wireless client debug bundle	Cisco IOS XE 17.11.1	Client debug bundle includes AP logs along with the existing controller bundle, collected in a tar file through a single **debug** command.

Types of logs collected

Types of logs collected details.

A log type is a diagnostic data category that

- groups related log files generated during client device troubleshooting
- distinguishes between control plane packet captures, AP logs, and client-specific traces, and
- determines the format and file structure used to collect and organize system diagnostics.

The client debug bundle logs are collected in tar file format on bootflash by using a single **debug** command.

This example displays the file formats of logs collected from a client device with MAC address 8cXX.90XX.fdXX:

Example :

The final tar file that is generated is wireless_bundle_123456_UTC_Oct_20_2022.tar.

These files are extracted from the wireless_bundle_123456_UTC_Oct_20_2022.tar file:

- wireless_bundle_8cXX.90XX.fdXX.tar (client radioactive trace debug log)

- epc_135790_UTC_Oct_20_2022.pcap (packet capture in a control plane)
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tgz (AP logs)

These files are extracted from wireless_bundle_8cXX.90XX.fdXX.tar client radioactive trace debug log file:

- show_tech_support_wireless_client_before_RA_start_8cXX.90XX.fdXX_134941_UTC_Oct_20_2022.txt
- ra_trace_8cXX.90XX.fdXX_135055_UTC_Oct_20_2022.log
- ra_trace_internal_8cXX.90XX.fdXX_135057_UTC_Oct_20_2022.log
- show_tech_support_wireless_client_after_RA_stop_8cXX.90XX.fdXX_135055_UTC_Oct_20_2022.txt

These files are extracted from ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tgz AP log file:

- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.messages
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.syslogs
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tech_cdb_0
- ap_3802_cisco_client_bundle.17.11.0.61.20221020.135154.tech_cdb_1

Collect wireless client debug bundle (CLI)

Collect wireless client debug bundle using commands.

Collect wireless client debug information for specified clients for troubleshooting using commands.

Procedure

1. Add client MAC addresses for which debug logs are required.

   Example

   ```
   Device# debug wireless bundle client mac aaaa.bbbb.cccc
   ```

   You can add up to 32 client MAC addresses to the command. To delete the MAC addresses, run the **no** form of this command.

2. Start the collection of the client debug bundle for wireless clients.

   Example

   ```
   Device# debug wireless bundle client start
   ```

3. Optional: Enable the AP archive collection on a site tag.

   Example

   ```
   Device# debug wireless bundle client start ap-archive site-tag default-site-tag
    level { critical | debug | error | verbose}
   ```

   This specifies the AP archive levels as well.

4. Optional: Enable embedded packet capture (EPC) in a control plane.

Example

```
Device# debug wireless bundle client start epc
```

> **Note**
>
> If EPC is already enabled and active from a different source, you cannot start the debug bundle with EPC. To use EPC with the debug bundle, stop EPC if it is enabled from a different source, and then restart it with the debug bundle.

5. Optional: Configure the maximum time, in minutes, to trace the condition.

   Example

   ```
   Device# debug wireless bundle client start monitor-time 30
   ```

   The default time is 30 minutes.

6. Optional: Stop the collection of the debug bundle for wireless clients.

   Example

   ```
   Device# debug wireless bundle client stop-all collect {all | mac H.H.H}
   ```

7. Optional: Cancel the collection of the debug bundle for wireless clients.

   Example

   ```
   Device# debug wireless bundle client abort
   ```

91 Aggressive Client Load Balancing

Topics:

- Aggressive client load balancing

Aggressive client load balancing

Introduces aggressive client load balancing, detailing how wireless clients are distributed across lightweight APs, client association redirection from congested APs, and optimized network performance through AP utilization management.

Aggressive client load balancing is a wireless network feature that

- distributes wireless clients across lightweight APs managed by the same controller
- redirects client association attempts from overutilized APs to less busy APs using standardized response codes, and
- helps optimize overall network performance by preventing AP overload.

Guidelines of aggressive client load balancing

When a wireless client attempts to associate to a lightweight AP, the associated response packets are sent to a client with an 802.11 response packet including status code 17. This code 17 indicates that the corresponding AP is busy. The AP does not respond with 'success' if the AP threshold is not met. If the AP utilization threshold is exceeded and another less busy AP hears the client request, the AP responds with code 17 (AP busy).

If AP1 has more clients than AP2 during the load-balancing window, AP1 is considered busier. When a client attempts to associate to AP1, the client receives an 802.11 response packet with status code 17, indicating that the AP is busy, and the client attempts to associate to a different AP.

Configure the controller to deny client associations up to 10 times. If a client tries to connect 11 times, it will connect on the 11th attempt. Enable or disable load balancing on a particular WLAN. This option is helpful if you need to exclude time-sensitive voice clients from load balancing.

Note

For a FlexConnect AP, the association is locally handled. The controller makes load-balancing decisions. A FlexConnect AP sends an initial response to the client before knowing the result of the calculations in the controller. Load balancing does not work when the FlexConnect AP is in standalone mode.

In this mode, the FlexConnect AP does not send a (re)association response with status 17 for load balancing. Instead, it first sends a (re)association response with status zero (success), and then sends a deauthentication with reason five.

Restrictions of aggressive client load balancing

- This feature is not supported on the APs joined on default-site-tag.
- This feature is not supported on the APs across different named site-tags.
- This feature is supported only on the APs within a named-site-tag.

Enable aggressive client load balancing (GUI)

Enable aggressive client load balancing using GUI.

Ensure clients are evenly distributed across APs to maximize WLAN performance using GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **WLANs** > **Wireless Networks**.

2. Select a **WLAN** to view the **Edit WLAN** window.
3. Click on the **Advanced** tab.
4. Check the **Load Balance** check box to enable the feature.
5. Click **Update & Apply to Device**.

Configure aggressive client load balancing (GUI)

Configure Aggressive Client Load Balancing using GUI.

Set the number of clients and denial count for aggressive load balancing to optimize wireless network performance using GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **Advanced**.

   The **Load Balancing** window appears.
2. In the **Aggressive Load Balancing Window (clients)** field, enter the number of clients for the aggressive load balancing client window.
3. In the **Aggressive Load Balancing Denial Count** field, enter the load balancing denial count.
4. Click **Apply**.

Configure aggressive client load balancing (CLI)

Configure aggressive client load balancing using commands.

Configure aggressive client load balancing to optimize WLAN performance and distribute clients across APs using commands.

Procedure

1. Enter the global configuration mode and specify the WLAN name.

   Example

   ```
   Device# configure terminal
   ```

   ```
   Device(config)# wlan test-wlan
   ```
2. Disable the WLAN.

   Example

   ```
   Device(config-wlan)# shutdown
   ```
3. Configure a guest controller as mobility controller, in order to enable client load balance to a particular WLAN.

Example

```
Device(config-wlan)# load-balance
```

Configure the WLAN security settings as the WLAN requirements.

4. Enable WLAN.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

5. Return to the privileged EXEC mode and enter the global configuration mode.

   Example

   ```
   Device(config)# end
   ```

   ```
   Device(config)# configure terminal
   ```

6. Configure the load balancing denial count.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} load-balancing denial 10
   ```

7. Configure the number of clients for the aggressive load balancing client window.

   Example

   ```
   Device(config)# ap dot11 {24ghz | 5ghz} load-balancing window 10
   ```

8. Return to the privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

9. Display a filtered section of the current configuration.

   Example

   ```
   Device# show running-config | section test-wlan
   ```

92 RF based Automatic AP Load Balancing

Topics:

- RF based automatic AP load balancing

RF based automatic AP load balancing

Introduces RF based automatic AP load balancing, detailing its operation using RRM neighbor report-based clustering, supported platforms and APs, prerequisites, use cases, feature history, and related commands for optimizing AP distribution and resource usage across WNCd instances.

RF based automatic AP load balancing is a wireless network load management feature that

- groups APs dynamically using RRM neighbor report-based AP grouping
- balances AP clusters across WNCd instances to optimize resource usage, and
- overrides site tag-based load balancing to ensure even AP distribution and prevent overload.

The RF based Automatic AP Load Balancing feature builds on the existing site tag-based load balancing feature. In the existing method, APs are balanced by assigning them to wireless network control daemons (WNCd) based on site tags. If the number of APs in a named site tag exceeds the capacity of a WNCd instance, uneven AP distribution may occur, which can result in high memory and CPU usage.

Limiting the number of APs in a site tag to 1000 using the **load** command may not prevent uneven distribution if the AP load limit is not correctly configured. In some cases, APs assigned to a site tag may not be colocated.

When you enable this feature, it forms AP clusters based on RSSI values from AP neighbor reports. The clusters are divided into sub-neighborhoods and smaller areas, which are then distributed evenly across WNCd processes. AP load balancing becomes active after you reboot the controller or perform an AP CAPWAP reset using the **ap neighborhood load-balance apply** command. When active, RF based Automatic AP Load Balancing overrides site tag-based load balancing.

Supported platforms

- Cisco Catalyst 9800-80 Wireless Controller
- Cisco Catalyst 9800-40 Wireless Controller
- Cisco Catalyst 9800 Wireless Controller for Cloud
- Catalyst 9800 Embedded Wireless Controller for a Cisco switch

Prerequisites for RF based automatic AP load balancing

Before enabling RF-based automatic AP load balancing, make sure your network is stable and all APs are fully deployed with enough time to discover all RF neighbors.

Use cases for RF based automatic AP load balancing

- You can use a single site tag for all deployed APs.
- If you attach more APs to a named-site tag than the available capacity of the WNCds, this feature provides better load balancing across WNCd instances.
- Use this feature in environments with many client intra-WNCd roaming scenarios. For instance, if you manage APs in two separate buildings on a campus, assign all APs for each building to a single WNCd rather than splitting them across multiple WNCds.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 97: Feature history for RF based automatic AP load balancing

Feature Name	Release Information	Feature Description
RF based automatic AP load balancing	Cisco IOS XE 17.12.1	The RF based Automatic AP Load Balancing feature uses Radio Resource Management (RRM) neighbor report-based AP grouping and load-balancing across WNCd instances. These commands are introduced: • apneighborhood load-balance • apneighborhood calendar-profile • wirelessload-balance ap method rf • showap neighborhood summary • showap neighborhood details • showap neighborhood • showap neighborhood mac details • showap neighborhood wncd

Restrictions and guidelines for RF based automatic AP load balancing

Restrictions for RF based automatic AP load balancing

- You cannot use the same calendar profile for AP neighborhood policy or AP profile.
- This feature is supported only on APs in local, fabric, and FlexConnect mode.
- You cannot run the feature when the overall load on the system is high.
- You cannot use the output of the **show wireless loadbalance tag affinity** command when the RF based automatic AP load balancing feature is enabled.

Guidelines for RF based Automatic AP Load Balancing

- For a new deployment, use the site tags and follow the current site tag recommendations to evenly distribute the APs, or use the **site tag load** command to automatically distribute the APs. Using site tags ensures that all APs with the same site tag are assigned to the same WNCd. This arrangement simplifies both troubleshooting and intra-WNCd roaming.
- If you cannot use site tags because grouping APs is not possible or you wish to avoid additional design work, select either the default site tag or any named site tag and enable the RF-based automatic AP load balancing feature.
- In an existing deployment, if high CPU usage results from an unbalanced system, use the auto RRM load balance system instead of redesigning site tags.
- If no CPU load issues exist, even though the system is unbalanced, maintain your current configuration.

Configure RF based automatic AP load balancing

Configure RF based automatic AP load balancing.

Achieve balanced AP distribution across wireless controllers using RF metrics through commands.

Before you begin

The enablement of the RF-based load-balancing algorithm involves two phases.

1. In the first phase, the running of the algorithm, the RF-based automatic AP load balancing feature can be scheduled to run when the calendar profile start time expires using the **ap neighborhood calendar-profile** command, or it can be started on-demand using the **ap neighborhood load-balance start** command. You can schedule the calendar profile start timer to run daily, weekly, or monthly.

   Note

   For more information on configuring Calendar profile, check Configure a calendar profile (GUI) on page 408 and Configure a calendar profile (CLI) on page 409.

2. To apply the algorithm, reload the controller or use the **ap neighborhood load-balance apply** command after the wireless load-balance ap method rf configuration is enabled.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP neighborhood calendar profile.

   Example

   ```
   Device(config)# ap neighborhood calendar-profile ap-calendar-profile
   ```

   Note

   After setting the calendar profile, you can choose to skip Step 4. If you want to perform load balancing immediately, complete Step 4.

3. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

4. Optional: Start AP neighborhood load-balance algorithm calculation and WNCd allocation.

Example

```
Device# ap neighborhood load-balance start
```

5. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

6. Configure RF-based AP load balancing.

   Example

   ```
   Device(config)# wireless load-balance ap method rf
   ```

7. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

8. Run on-demand RRM-based AP load balancing.

   Example

   ```
   Device# ap neighborhood load-balance apply
   ```

   This command rebalances the APs by performing a CAPWAP reset. If an AP is already assigned to the correct WNCd instance, it is not reset. You cannot execute this command if the RRM-based AP load balancing algorithm is running or if algorithm results are unavailable.

Disable RF based automatic AP load balancing (CLI)

Disable RF based Automatic AP Load Balancing.

Disable the RF-based automatic AP load balancing feature to prevent APs from using RF data to evenly distribute clients and APs using commands.

Before you begin

The APs may remain load balanced based on algorithm data, even after you disable all feature configurations and clear all algorithm outputs. To rebalance all APs using the default method of site tags, reload the controller or perform a CAPWAP reset on all APs.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Disable RF-based AP load balancing.

   Example

   ```
   Device(config)# no wireless load-balance ap method rf
   ```

3. Disable the AP neighborhood calendar profile.

   Example

   ```
   Device(config)# no ap neighborhood calendar-profile ap-calendar-profile
   ```

4. Return to the privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

5. Clear the AP neighborhood load-balance algorithm calculation and resource allocation.

   Example

   ```
   Device# ap neighborhood load-balance clear
   ```

Verify automatic WNCd load balancing

Verify automatic WNCd load balancing.

To verify the results of the RF-based algorithm and the result of the related load balancing, use these**show** commands.

To view the AP neighborhood summary, use this **show** command:

```
Device# show ap neighborhood summary
NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood
Total number of neighborhood: 5
Total number of algorithm iterations: 1
Ideal AP capacity per WNCD instance: 210
Total number of neighborhood area: 14
NH-ID      AREA-ID         Process Name   Number of APs
-------------------------------------------------
0          0x00000000      WNCD_1         1
1          0x00000000      WNCD_0         2
2          0x00000000      WNCD_0         100
2          0x00000001      WNCD_0         100
2          0x00000002      WNCD_3         100
2          0x00000003      WNCD_4         50
3          0x00000000      WNCD_1         100
3          0x00000001      WNCD_1         100
3          0x00000002      WNCD_4         100
3          0x00000003      WNCD_4         50
4          0x00000000      WNCD_2         100
4          0x00000001      WNCD_2         100
4          0x00000002      WNCD_3         100
4          0x00000003      WNCD_3         50
```

To view the AP neighborhood details, use this **show** command:

```
Device# show ap neighborhood details
NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood
Number of APs: 4
NH-ID   AREA-ID        WNCD instance    AP Name                 Ethernet MAC

-------------------------------------------------------------------------------
0       0x00000000     1               EDU_BR_01_00_28_3702    bc16.6509.bfcc

1       0x00000000     0               ci-glad-mdns-ap         0cd0.f894.567c

1       0x00000000     0               EDU_VW_9120_1_2         c4f7.d54c.f978

2       0x00000000     0               ewlc-hc-tsim-30-1       00b9.3000.02f0
```

To view the AP neighborhood information, use this **show** command:

```
Device# show ap neighborhood 0 details
NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood
Number of APs: 1
NH-ID     AREA-ID          WNCD instance     AP Name              Ethernet MAC

-------------------------------------------------------------------------------
0         0x00000000       0               APA023.9FD8.EA22     a023.9fd8.ea22
```

To view the AP neighborhood details using its MAC address, use this **show** command:

```
Device# show ap neighborhood mac 0aa8.89f0.0001 details
NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood
AP Name            Ethernet MAC    Radio MAC       NH-ID  AREA-ID     WNCD
instance
-------------------------------------------------------------------------------
AP6B8B4567-0001    0aa8.89f0.0001  0aa8.8900.0100  0      0x00000000  0
```

To view the WNCd information, use this **show** command:

```
Device# show ap neighborhood wncd 0 details
NH-ID = Neighborhood ID
AREA-ID = Area ID of neighborhood
Number of APs: 9
WNCD instance     NH-ID       AREA-ID          AP Name          Ethernet MAC

-------------------------------------------------------------------------------
0                 2           0x00000000       9130I-1          0c75.bdb5.ffc0

0                 2           0x00000000       9130E-2          3c41.0efe.46f0

0                 2           0x00000000       9120E-2          5ce1.7628.8bbc

0                 2           0x00000000       9130I-2          e44e.2d2e.59d4

0                 2           0x00000000       9120E-1          5ce1.7628.aa0c

0                 2           0x00000000       9120E-3          5ce1.7628.af04
```

```
0                2           0x00000000       3700I-2          b838.6159.dfa4

1                0           0x00000000       3800I-2          6cb2.ae2e.dfdc

93 Accounting Identity List

Topics:

- Configure accounting identity list (GUI)

Configure accounting identity list (GUI)

Configure accounting identity list using GUI.

Create a method list for accounting identity using the GUI to control and monitor user access to your network.

Procedure

1. Choose **Configuration** > **Security** > **AAA**.
2. In the **AAA Method List** tab, go to the **Accounting** section, and click **Add**.
3. In the **Quick Setup: AAA Accounting** window that is displayed, enter a name for your method list.
4. Select the type of authentication as identity, in the **Type** drop-down list.
5. Choose the server groups you want to use to authenticate access to your network, from the **Available Server Groups** list and click **>** icon to move them to the **Assigned Server Groups** list.
6. Click **Save & Apply to Device**.

Configure accounting identity list (CLI)

Configure accounting identity list using commands.

Enable RADIUS accounting with an identity list to log user actions and network usage events using commands.

When a user successfully executes an action, the RADIUS accounting server logs the changed attributes, user ID, remote host, date and time of execution, authorization level, description of the action performed, and values provided.

Follow the procedure given below to configure accounting identity list.

Before you begin

Configure the RADIUS server and AAA group server.

Procedure

Enable accounting to send a start-record accounting notice when a client is authorized and a stop-record at the end.

Example

```
Device(config)# aaa accounting identity user1 start-stop group aaa-test
```

Note

You can also use the default list, instead of a named list.

Configure client accounting (GUI)

Configure client accounting using GUI.

Enable client accounting on a specified policy profile through the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click the **Policy Profile Name**. In the **Edit Policy Profile** window, go to the **Advanced** tab.
3. From the **Accounting List** drop-down, select the appropriate accounting list for this policy profile. The policy profile uses the accounting type you selected before gaining access to the network.
4. Click **Save & Apply to Device**.

Configure client accounting (CLI)

Configure client accounting using commands.

Enable client accounting on a WLAN policy profile to track user activity and support auditing with an accounting server using commands.

Procedure

1. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

2. Disable the policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

3. Set the accounting list.

   Example

   ```
   Device(config-wireless-policy)# accounting-list user1
   ```

4. Enable the policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

94 Accounting Session ID

Topics:

- Accounting session ID

Accounting session ID

Introduces the accounting session ID for wireless client sessions, explains its generation and role in AAA, and outlines its feature history, including changes in support across Cisco IOS XE releases.

An accounting session ID is a wireless client session identifier that

- is unique for each client session
- identifies the accounting data for a wireless client in the AAA server, and
- is generated by the AAA module during session establishment.

Feature history

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 98: Feature history for Accounting session ID

Feature Name	Release Information	Feature Description
Accounting session ID	Cisco IOS XE 17.4.1	With this feature, accounting session ID is supported in the AAA access request, while authenticating wireless client using IEEE 802.1x method. From this release, the accounting session ID is sent as part of the access request too.
Accounting session ID	Cisco IOS XE 17.3.x	In the Cisco IOS XE release 17.3.x and earlier releases, the accounting session ID was sent only as part of the accounting request.

Configure an accounting session ID (CLI)

Configure an accounting session ID using commands.

Set up an accounting session ID on your device to track accounting sessions and include session identification attributes in RADIUS packets using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Send the RADIUS authentication attribute 44, in the access request packet.

Example

```
Device(config)# radius-server attribute wireless 44 include-in-access-req
```

3. Configure the accounting session identity of the AAA server.

Example

```
Device(config)# aaa accounting identity accounting-list-name start-stop group
 AAA_GROUP_1
```

4. Configure the WLAN policy profile.

Example

```
Device(config)# wireless profile policy default-policy-profile
accounting-list-name start-stop group AAA_GROUP_1
```

5. Configure the accounting list.

Example

```
Device(config-wireless-policy)# accounting-list accounting-list-name
```

> **Note**
>
> The accounting session ID is included in the account request only when the **radius-server attribute wireless 44 include-in-access-req** command is enabled and the accounting configuration is set under the wireless policy.

6. Add a description for the policy profile.

Example

```
Device(config-wireless-policy)# description accounting-description
```

7. Configure the VLAN name or ID.

Example

```
Device(config-wireless-policy)# vlan 40
```

8. Save the configuration, exit configuration mode and return to privileged EXEC mode.

Example

```
Device(config-wireless-policy)# no shutdown
```

Verify an account session ID

Verify an account session ID.

To verify if an account session ID is populated, use this command:

```
Device# show wireless pmk-cache

Number of PMK caches in total : 1
Type      Station            Entry Lifetime  VLAN Override        IP Override
         Accounting-Session-Id   Audit-Session-Id              Username
-----------------------------------------------------------------------------------------------------------
RSN       6c19.c0e6.a444      1768            NA
           0x00000006              052DA8C1000000104E634C77      cwa-user
```

To display the current Accounting Session ID, use this command:

```
Device# show wireless client mac-address <H.H.H> detail

Central NAT : DISABLED
Session Manager:
  Point of Attachment :CAPWAP_90000005
  IIF ID             : 0x90000005
  Authorized         : TRUE
  Session timeout    : 1800
  Common Session ID: 000000000000000B14E9130A
  Acct Session ID  : 0x0000000c
  Last Tried Aaa Server Details:
        Server IP : 192.0.2.1
  Auth Method Status List
        Method : Dot1x
                SM State         : AUTHENTICATED
                SM Bend State    : IDLE
  Local Policies:
        Service Template : wlan_svc_default-policy-profile (priority 254)
                VLAN             : 1
  Server Policies:
                Absolute-Timer   : 1800
  Resultant Policies:
                VLAN Name        : default
                VLAN             : 1
                Absolute-Timer   : 1800
```

95 Interim Accounting

Topics:

- Interim accounting

Interim accounting

Outlines interim accounting update mechanisms in RADIUS, including event-triggered and periodic updates, session parameter reporting, reasons to disable the feature, and feature history with release details for Cisco IOS XE Cupertino 17.9.1.

An interim accounting update is a RADIUS accounting message that

- reports changes to key session parameters such as DHCP, HTTP, IP, or roaming state
- is sent by the network access server (NAS) to the RADIUS server between the start-stop accounting messages, and
- can be triggered by specific events or at periodic intervals.

Note

The RADIUS accounting requests send data, such as VLAN ID, authentication methods, and so on, to a session.

RADIUS accounting covers these updates:

- Interim Updates: When RADIUS accounting covers DHCP_TLVs, HTTP_TLVs, IP, or ROAM (state machine) changes, the updates are referred to as interim updates or interim accounting.
- Periodic Updates: When RADIUS accounting is specified by a timer value, the updates are referred to as periodic updates.

Disable the interim updates for these reasons:

- These actions increase network congestion by sending unneeded traffic.
- They drive up error rates.
- They impact alarm thresholds and other metrics that are used for venue-authentication performance.

By default, the interim accounting feature is enabled with the **aaa accounting Identity default start-stop group radius** command.

Feature history for interim accounting

Disable interim accounting (CLI)

Disable interim accounting using commands.

Disable interim accounting on a WLAN policy profile using commands.

Before you begin

You must disable the Policy Profile before performing this procedure.

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure WLAN policy profile and enter wireless policy configuration mode.

Example

```
Device(config)# wireless profile policy default-policy-profile
```

3. Disable interim accounting.

Example

```
Device(config-wireless-policy)# no accounting-interim
```

4. Return to the privileged EXEC mode.

Example

```
Device(config-wireless-policy)# end
```

Verify interim accounting

Verify interim accounting.

To verify the interim accounting updates, run this command:

```
Device# show wireless profile policy detailed default-policy-profile | s Interim
Interim Accounting Updates: DISABLED
```

96 Wireless Multicast

Topics:

- Wireless multicast
- IPv6 snooping
- IPv6 multicast over multicast
- Directed multicast service
- Restrictions for wireless broadcast, non-IP multicast and multicast VLAN
- Multicast filtering

Wrapper for Wireless Multicast chapter in vEWLC config guide.

Wireless multicast

Outlines wireless multicast communication methods and modes on controllers, including unicast, multicast, and FlexConnect operation, and details IGMP snooping, MGID assignment, and multicast traffic optimization for APs and clients.

A wireless multicast is a wireless network communication method that

- allows simultaneous transmission of data from a controller to multiple APs and clients
- operates in different modes (unicast and multicast) to accommodate network capabilities and efficiency, and
- leverages features such as IGMP snooping and MGID assignment to optimize multicast traffic delivery.

If the network supports packet multicasting, the multicast method that the controller uses can be configured. The controller performs multicast routing in two modes:

- Unicast mode: The controller unicasts every multicast packet to every AP associated with the controller. Although this mode is inefficient and generates significant extra traffic for the device and the network, it is required on networks that do not support multicast routing. This need arises if the APs are on different subnets than the device's wireless management interface.
- Multicast mode: The controller sends multicast packets to a CAPWAP multicast group. This method reduces the overhead on the controller processor by shifting the work of packet replication to the network. This approach is much more efficient than the unicast method.

The FlexConnect mode has two submodes: local switching and central switching. In local switching mode, data traffic is switched at the AP level and the controller does not process any multicast traffic. In central switching mode, multicast traffic reaches the controller. IGMP snooping, however, takes place at the AP.

When multicast mode is enabled and the controller receives a multicast packet from the wired LAN, it encapsulates the packet using CAPWAP and forwards it to the CAPWAP multicast group address. The controller always uses the management VLAN to send multicast packets. APs in the multicast group receive these packets and forward them to all BSSIDs mapped to the VLAN that delivers multicast traffic to clients.

The controller supports all capabilities of IGMP v1, including multicast listener discovery (MLD) v1 snooping. However, IGMP v2 and IGMP v3 support is limited. This feature tracks and delivers IPv6 multicast flows to clients that request them. For IPv6 multicast, you must enable global multicast mode.

Internet group management protocol (IGMP)

IGMP snooping is a network switch feature that

- listens to IGMP network traffic between hosts and routers
- maintains a map of which devices are subscribed to which multicast groups, and
- forwards multicast traffic only to the relevant devices, reducing unnecessary data transmission.

When this feature is enabled, the controller gathers IGMP reports from clients, processes them, creates unique multicast group IDs (MGIDs) based on the Layer 3 multicast address and VLAN number, and sends the IGMP reports to the IGMP querier. The controller then updates the AP MGID table on the corresponding AP with the client MAC address.

When the controller receives multicast traffic for a particular multicast group, it forwards the traffic to all APs. However, only those APs with active clients subscribed to that multicast group send multicast traffic on the specified WLAN. IP packets are forwarded with an MGID unique to both the ingress VLAN and the destination multicast group. Layer 2 multicast packets are forwarded with an MGID unique to the ingress VLAN.

An MGID is a 14-bit value placed in the 16-bit reserved field of wireless information in the CAPWAP header. The remaining two bits must be set to zero.

Multicast optimization

This section provides multicast optimization details.

Multicast optimization enables you to create a multicast VLAN that can be used for multicast traffic. One of the VLANs in the device can be configured as a multicast VLAN where multicast groups are registered. Clients can listen to a multicast stream on the multicast VLAN. The system generates the MGID based on both the multicast VLAN and the multicast IP addresses.

- If multiple clients on different VLANs of the same WLAN listen to a single multicast IP address, the system generates a single MGID. The device forwards all multicast streams from clients on this VLAN group through the multicast VLAN. This approach ensures that the upstream router has one entry for all VLANs in the group.
- Only one multicast stream reaches the VLAN group, even when clients are on different VLANs. Therefore, the device sends out just one multicast stream over the network.

Note

When VLAN groups are defined and use multicast communication, you must enable the multicast VLAN.

IPv6 global policies

This section provides IPv6 global policies details.

- IPv6 global policies provide storage and access policy database services. IPv6 ND inspection and IPv6 RA guard are features provided by IPv6 global policies that you can enable. When you configure ND inspection globally, the policy attributes are stored in the software policy database. You can then apply the policy to an interface. The software policy database updates its entry to record the interface that you applied the policy to.
- The controller enables IPv6 RA guard by default. If Stateless Address Auto-Configuration (SLAAC) is deployed in your network, forward route advertisements (RA) from the wired side to wireless clients.

Prerequisites for configuring wireless multicast

This section describes the prerequisites for configuring wireless multicast.

IP multicast routing must be enabled and the PIM version and PIM mode must be configured. The default routes should be available in the device. After performing these tasks, the device can forward multicast packets and populate its multicast routing table. To configure multicast mode, the network should be enabled for multicast.

- Multicast hosts, routers, and multilayer switches must have IGMP enabled to participate in IP multicasting.
- When enabling multicast mode on the controller, a CAPWAP multicast group address should also be configured. APs use IGMP to listen to the CAPWAP multicast group.
- You must be cautious when using IGMPv3 with switches enabled for IGMP snooping. The IGMPv3 messages are different from the messages used in IGMP Version 1 (IGMPv1) and Version 2 (IGMPv2). If your switch does not recognize IGMPv3 messages, the hosts do not receive traffic when IGMPv3 is used.
- IGMPv3 devices do not receive multicast traffic if IGMP snooping is disabled or if IGMPv2 is configured on the interface.
- It is recommended to enable IGMPv3 on all intermediate or Layer 3 network devices, especially on each subnet used by multicast devices, such as controller and AP subnets.

Restrictions on configuring wireless multicast

This section describes configuring wireless multicast restrictions.

These are the restrictions for configuring IP multicast forwarding:

- APs in monitor mode, sniffer mode, or rogue-detector mode do not join the CAPWAP multicast group address.
- Each controller should be configured with a distinct CAPWAP multicast group.
- Do not enable multicast routing on the management interface.
- Multicast with VLAN groups is supported only in APs operating in local mode.
- The uplink switch should route multicast traffic from wireless clients within a VLAN that is not configured for multicast.
- The wireless multicast to unicast (MCUC) mode is only supported in 9800-CL small template.
- Cisco IOS XE 17.9.5, 17.12.2, 17.14, and later versions support multicast traffic on an AAA-overridden VLAN.
- Multicast-unicast is not supported on large-scale controller appliances, including CW9800L, CW9800M, CW9800H1, and CW9800H2.
- Multicast is not supported over mobility tunnels.

Configuring wireless multicast

This section describes the various wireless multicast configuration tasks.

These sections provide information about the various wireless multicast configuration tasks:

Configure wireless multicast-MCMC mode (CLI)

Configure wireless multicast-MCMC mode using commands.

Enable wireless multicast in multicast-over-multicast (MCMC) mode on your device using commands.

Procedure

1. Enable multicast-over-multicast.

   Example

   ```
   Device(config)# wireless multicast 224.0.0.1
   ```

   Use the **no** form of this command to disable the feature.

2. Exit the configuration mode.

   Example

   ```
   Device(config)# end
   ```

Configure wireless multicast-MCUC mode (CLI)

Configure wireless multicast-MCUC mode using commands.

Enable multicast traffic for wireless clients in MCUC mode using commands.

> **Note**
>
> The wireless multicast to unicast (MCUC) mode is only supported in 9800-CL small template.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable multicast traffic for wireless clients.

   Example

   ```
   Device(config)# wireless multicast
   ```

3. Exit the configuration mode.

   Example

   ```
   Device(config)# end
   ```

Configure multicast listener discovery snooping (GUI)

Configure multicast listener discovery snooping using GUI.

Enable or disable multicast listener discovery (MLD) snooping on specific VLANs to efficiently manage multicast network traffic using commands.

Procedure

1. Choose **Configuration** > **Services** > **Multicast**.
2. Click **MLD Snooping**.
3. In the **MLD Snooping** section, click the toggle button to enable or disable MLD snooping.
4. Enter the **MLD Query Interval** in milliseconds. The valid value range is between 100 ms and 32767 ms. The default value is 1000 ms.
5. Move the required VLAN IDs from the **Disabled** section to the **Enabled** section. By default, this feature is disabled on all VLANs.

   You can also search for a VLAN ID using the search field. Click **Disable All** to move all the VLAN IDs from the **Enabled** list to the **Disabled** list. Click **Enable All** to move all the VLAN IDs from the **Disabled** list to the **Enabled** list.

6. Click **Apply to Device**.

Configure IPv6 MLD snooping (CLI)

Configure IPv6 MLD snooping using commands.

Enable MLD snooping on your device to optimize IPv6 multicast traffic traversal using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# ipv6 mld snooping
   ```

2. Enable MLD snooping.

   Example

   ```
   Device(config)# ipv6 mld snooping
   ```

Verify the multicast VLAN configuration

Verify the multicast VLAN configuration.

To view the multicast VLAN associated with a policy profile along with the VLAN assigned to that profile, use this command:

```
Device# show wireless profile policy detail default-policy-profile
Policy Profile Name           : default-policy-profile
Description                   : default policy profile
Status                        : ENABLED
VLAN                          : vlan-pool1
                Multicast VLAN : 84
Client count                  : 0
Passive Client                : DISABLED
```

To view the multicast VLAN associated with a client, use this command:

```
Device# show wireless client mac ac2b.6e4b.551e detail
Client MAC Address : ac2b.6e4b.551e
Client IPv4 Address : 192.0.2.20
…….
VLAN : 82
Access VLAN : 82
                Multicast VLAN: 84
```

IPv6 snooping

Outlines the operation of IPv6 snooping and IPv6 neighbor discovery inspection, detailing mechanisms for learning and securing IPv6 address-to-MAC bindings, traffic analysis, vulnerability mitigation, hardware capture rules, and traffic classification to enhance Layer 2 security and scalability.

IPv6 snooping or IPv6 neighbor discovery inspection is a Layer 2 security feature that

- combines several IPv6 first-hop security mechanisms, including IPv6 Address Glean and IPv6 Device Tracking
- learns and secures IPv6 address-to-MAC bindings using neighbor discovery messages, and
- mitigates vulnerabilities such as attacks on duplicate address detection (DAD), address resolution, device discovery, and the neighbor cache in the neighbor discovery process by analyzing and filtering ND protocol traffic based on trusted binding tables

IPv6 neighbor discovery (ND) inspection operates at Layer 2, or between Layer 2 and Layer 3, providing IPv6 features with security and scalability.

IPv6 ND inspection learns and secures bindings for stateless autoconfiguration addresses in Layer 2 neighbor tables and analyzes ND messages to build a trusted binding table. IPv6 ND messages that do not have valid bindings are dropped. An ND message is considered trustworthy if its IPv6-to-MAC mapping can be verified.

When IPv6 ND inspection is configured on a target which can include device ports, switch ports, Layer 2 interfaces, Layer 3 interfaces, or VLANs (depending on platform support), the device downloads capture instructions to the hardware. These instructions redirect ND protocol and Dynamic Host Configuration Protocol (DHCP) for IPv6 traffic to the switch integrated security features (SISF) infrastructure in the routing device. For ND traffic, messages such as NS, NA, RS, RA, and REDIRECT are directed to SISF. For DHCP, UDP messages sourced from port 546 or 547 are also redirected.

IPv6 ND inspection registers its 'capture rules' with the classifier, which aggregates all rules from all features on a given target and installs the corresponding ACL into the platform-dependent modules. When redirected traffic is received, the classifier calls all entry points from registered features for the relevant target, including the IPv6 ND inspection entry point. The IPv6 ND inspection entry point is called last. If another feature makes a decision, such as to drop the traffic, that decision overrides the IPv6 ND inspection action.

IPv6 device tracking

This topic describes the IPv6 device tracking details.

- IPv6 device tracking provides IPv6 host liveness tracking.
- This initiates a neighbor table to immediately update when an IPv6 host disappears.

IPv6 first-hop security binding table

IPv6 First-Hop Security Binding Table details.

An IPv6 first-hop security binding table is a security database that

- enables the binding table to recover in the event of a device reboot populating from information sources such as neighbor discovery (ND) snooping and DHCP gleaning
- stores entries that map IPv6 neighbors to validate the link-layer addresses (LLA), IPv6 or IPv4 addresses, prefix binding, and
- is used by IPv6 guard features to validate bindings and prevent spoofing or redirect attacks.

The recovery mechanism will block any data traffic sourced from an unknown source; that is, a source not already specified in the binding table and previously learned through ND or DHCP gleaning. When the destination guard cannot resolve a destination address, this feature recovers the missing binding table entries. When a failure occurs, a binding table entry is recovered by querying the DHCP server or the destination host, depending on the configuration.

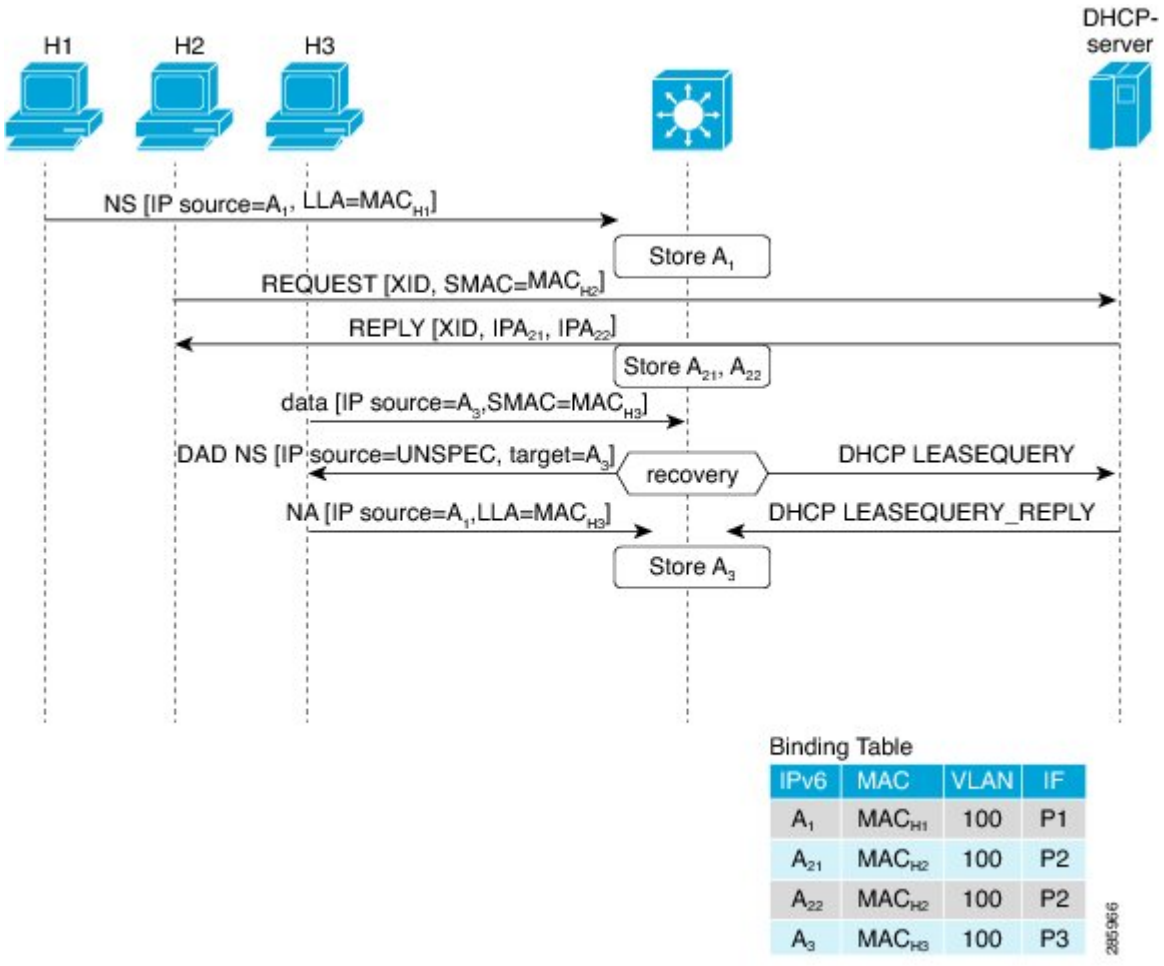
Recovery protocols and prefix lists

This section provides recovery protocols and prefix lists details.

The IPv6 first-hop security binding table recovery mechanism allows you to configure a prefix list. This list is matched before recovery is attempted for both DHCP and NDP.

- If an address does not match the prefix list associated with the protocol, recovery of the binding table entry with that protocol is not attempted. The prefix list must match the prefixes that are valid for address assignment in the Layer 2 domain for the given protocol.
- By default, no prefix list is configured, so recovery is attempted for all addresses. The command to associate a prefix list to a protocol is **protocol { dhcp | ndp} [prefix-list prefix-list-name]**.

IPv6 address glean



IPv6 address glean details.

An IPv6 address glean feature is an IPv6 security mechanism that

- inspects Neighbor Discovery (ND) and DHCP messages on a link to discover glean IPv6 addresses
- populates the binding table with gleaned addresses to enable accurate tracking, and
- enforces address ownership, limiting the number of addresses claimed by any node.

This figure shows how IPv6 address glean works.

Figure 8: IPv6 Address Glean

Restrictions for IPv6 snooping

This section describes the restrictions for IPv6 snooping.

The IPv6 snooping feature is not supported on EtherChannel ports.

IPv6 multicast over multicast

Outlines the configuration and mechanism of IPv6 multicast over multicast tunnels for wireless controllers, detailing AP participation, dual-protocol environments, tunnel types, mixed mode limitations, and multicast support across Cisco Catalyst 9800 platforms.

A multicast-over-multicast tunnel is a network transmission mechanism that

- enables a wireless controller to efficiently deliver IPv6 multicast traffic to multiple APs simultaneously
- ensures all APs join the same IPv6 multicast address for coordinated data flow, and
- supports deployment in environments where APs may connect via both IPv4 and IPv6 protocols.

When IPv6 multicast over multicast is configured, all APs join the IPv6 multicast address. The multicast traffic from the wireless controller to the APs then flows over the IPv6 multicast tunnel.

The IPv4 APs use a unicast IPv4 CAPWAP tunnel and join the IPv4 multicast group. The IPv6 APs use a unicast IPv6 CAPWAP tunnel and join the IPv6 multicast group.

> **Note**
>
> Cisco IOS XE Gibraltar 16.10.1 does not support mixed mode for Multicast over Unicast and Multicast over Multicast over IPv4 and IPv6.

Table 99: Multicast support per platform

Platform	Multicast support - multicast over unicast	Multicast support - multicast over multicast
Cisco Catalyst 9800-40 Wireless Controller	No	Yes
Cisco Catalyst 9800-80 Wireless Controller	No	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Small Template	Yes	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Medium Template	No	Yes
Cisco Catalyst 9800 Wireless Controller for Cloud - Large Template	No	Yes
Cisco Catalyst 9800-L Wireless Controller	Yes	Yes

Configure IPv6 multicast-over-multicast (GUI)

Configure IPv6 multicast-over-multicast using GUI.

Enable IPv6 multicast-over-multicast for APs to optimize multicast traffic delivery using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **Multicast**.
2. From the **AP Capwap Multicast** drop-down list, select **Multicast**.
3. Enter the **AP Capwap IPv6 Multicast group Address**.
4. Click **Apply**.

Configure IPv6 multicast-over-multicast (CLI)

Configure IPv6 multicast-over-multicast using commands.

Enable IPv6 multicast-over-multicast functionality on your device using commands.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure IPv6 multicast-over-multicast address.

   Example

   ```
   Device(config)# wireless multicast {ipv4 ipv4-address| ipv6 ipv6-address}
   ff45:1234::86
   ```

Verify IPv6 multicast-over-multicast

Verify IPv6 multicast-over-multicast.

To verify the IPv6 multicast-over-multicast configuration, use these commands:

```
Device# show wireless multicast
Multicast : Enabled
AP Capwap Multicast : Multicast
AP Capwap IPv4 Multicast group Address : 231.1.1.1
AP Capwap IPv6 Multicast group Address : ff45:1234::86
Wireless Broadcast : Disabled
Wireless Multicast non-ip-mcast : Disabled
```

```
Device# show running-configuration | inc multicast
show run | inc multicast:--
```

```
wireless multicast
wireless multicast ipv6 ff45:1234::86
wireless multicast 231.1.1.1
```

Verify the multicast connection between the controller and the AP

Verify the multicast connection between the controller and the AP.

The Cisco Catalyst 9800 Series Wireless Controller initiates a ping request. This request passes through the CAPWAP multicast tunnel to reach the CAPWAP multicast receiver, which is the AP. In response, the AP sends ping packets to the CAPWAP multicast group IP address and returns the response to the controller.

- View the statistics for transmitted and received traffic on the AP to analyze the data sent through the multicast tunnel.
- To verify multicast tunnel activity, enhance the statistics on the AP. The enhanced statistics show joins, leaves, and data packets transmitted and received through the multicast tunnel.

To confirm if the APs receive multicast to multicast (mom) traffic sent by the controller, use this command:

```
Device# show ap multicast mom
AP Name                      MOM-IP     TYPE MOM- STATUS
-----------------------------------------------------
SS-E-1                       IPv4             Up
SS-E-2                       IPv4             Up
9130E-r3-sw2-g1012           IPv4             Up
9115i-r3-sw2-te1-0-38        IPv4             Up
AP9120-r3-sw3-Gi1-0-46       IPv4             Up
ap3800i-r2-sw1-te2-0-2       IPv4             Up
```

Directed multicast service

Introduces directed multicast service, explaining how APs transmit multicast packets as unicast frames to improve delivery and battery life for clients, and lists supported Cisco Aironet AP models.

A directed multicast service is a wireless networking feature that

- enables APs to transmit multicast packets as unicast frames to clients
- allows clients to reliably receive multicast packets that were missed during sleep mode (for battery savings), and
- improves packet delivery rates and battery life by sending unicast frames at higher wireless link rates.

After receiving this request, an AP buffers multicast traffic for the client. When the client wakes up, the AP transmits the buffered traffic as a unicast frame. The AP can transmit the unicast frames to the client at a higher wireless link rate. Without DMS, the client has to wake up at each Delivery Traffic Indication Map (DTIM) interval to receive multicast traffic.

Configure directed multicast service (GUI)

Configure directed multicast service using GUI.

Enable directed multicast service on a specific WLAN to optimize multicast traffic delivery using the GUI.

Procedure

1. Choose **Configuration** > **Wireless** > **WLANs** > **Wireless Networks**.
2. Select a **WLAN** to view the **Edit WLAN** window.

3. Click on the**Advanced** tab.
4. Check the **Directed Multicast Service** check box to enable the feature.
5. Click **Update & Apply to Device**.

Configure directed multicast service (CLI)

Configure directed multicast service using commands.

Enable directed multicast service (DMS) on a WLAN to improve multicast efficiency for 802.11v-capable clients using commands.

Before you begin

- This feature is enabled on receiving a request from a client. Make sure to configure this feature under WLAN.
- It is supported only on 802.11v-capable clients, such as Apple iPad and Apple iPhone.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN profile and enter the WLAN profile configuration mode.

   Example

   ```
   Device(config)# wlan test5
   ```

3. Disable the WLAN profile.

   Example

   ```
   Device(config-wlan)# shutdown
   ```

4. Configure DMS processing per WLAN.

   Example

   ```
   Device(config-wlan)# dms
   ```

5. Enable the WLAN profile.

   Example

   ```
   Device(config-wlan)# no shutdown
   ```

Verify the directed multicast service configuration

Verify the directed multicast service configuration.

To verify the status of the DMS configuration on the controller, use these commands below. The DMS status is displayed under *IEEE 802.11v Parameters*.

```
Device# show wlan id 5
WLAN Profile Name     : test
==============================================
Identifier                                    : 5
Network Name (SSID)                           : test
Status                                        : Disabled
Broadcast SSID                                : Enabled
Universal AP Admin                            : Disabled

Partial BSS Color                           : unknown
BSS Color Code
```

To verify the status of the DMS configuration on the controller for clients, use this command:

```
Device# show wireless client mac-address 6c96.cff2.83a0 detail | inc 11v
11v BSS Transition : implemented
11v DMS Capable : Yes
```

To verify the DMS request and response statistics, use this command:

```
Device# show wireless stats client detail | inc DMS
Total DMS requests received in action frame      : 0
Total DMS responses sent in action frame         : 0
Total DMS requests received in Re-assoc Request  : 0
Total DMS responses sent in Re-assoc Response    : 0
```

To verify the DMS configuration Cisco Aironet 2700 and 3700 Series APs, use this command:

```
AP# show controllers dot11Radio 0/1 | begin Global DMS
Global DMS - requests:0 uc:0 drop:408
DMS enabled on WLAN(s): dms-open
 test-open
```

To verify the DMS configuration on the Cisco Aironet 2800, 3800, and 4800 Series APs, use this command:

```
AP# show multicast dms all
 vapid    client               dmsid        TClas
 0      1C:9E:46:7C:AF:C0     1    mask:0x55, version:4, proto:0x11, dscp:0x0,
 sport:0, dport:9, sip:0.0.0.0, dip:224.0.0.251
```

Restrictions for wireless broadcast, non-IP multicast and multicast VLAN

Outlines restrictions for wireless broadcast, non-IP multicast, and multicast VLAN, including limitations on VLAN groups, VLAN pool mappings, and forwarding of non-IPv4 multicast and broadcast traffic.

Restrictions

- Wireless broadcast does not support VLAN groups.
- If you map a VLAN pool to a WLAN profile, you cannot forward non-IPv4 multicast or broadcast traffic.
- Non-IPv4 multicasts and broadcasts are only available to clients on the VLAN you mapped to the WLAN. You cannot forward them on VLANs defined by AAA override.

Configure non-IP wireless multicast (CLI)

Configure non-IP wireless multicast using commands.

Enable non-IP multicast traffic on wireless VLANs using commands.

Before you begin

- The non-IP Multicast feature is disabled globally by default.
- To allow traffic to pass for non-IP multicast, you must enable global wireless multicast.
- This feature is not supported in Fabric or Flex deployments.

Procedure

1. Enable non-IP multicast in all the VLANs.

   Example

   ```
   Device(config)# wireless multicast non-ip
   ```

   By default, the non-IP multicast in all the VLANs is in disabled state. You must enable wireless multicast for traffic to pass. Use the **no** form of this command to disable non-IP multicast in all the VLANs.

2. Enable non-IP multicast per VLAN.

Example

```
Device(config)# wireless multicast non-ip vlan 5
```

By default, non-IP multicast per VLAN is disabled. Both wireless multicast and wireless multicast non-IP must be enabled to allow traffic to pass. Use the **no** form of this command to disable non-IP multicast per VLAN.

3. Exit the configuration mode.

Example

```
Device(config)# end
```

Configure wireless broadcast (GUI)

Configure wireless broadcast using GUI.

Enable broadcast packets for wireless clients on selected VLANs using the GUI.

Procedure

1. Choose **Configuration** > **Services** > **Multicast**.
2. On the Multicast page, enable **Wireless Broadcast** to allow packet transmission for wireless clients.

   The default value is disabled.
3. In the Disabled VLAN table, click the arrow next to the VLAN ID to change its status from **Disabled** to **Enabled**. This enables broadcast packets for the selected VLAN.

   The default value is disabled.
4. Save the configuration.

Configure wireless broadcast (CLI)

Configure wireless broadcast using commands.

Enable wireless clients to receive specific broadcast packets on the network using commands.

Before you begin

- This feature applies only to non-ARP and DHCP broadcast packets.
- By default, the feature is disabled globally.
- The feature is not supported in Fabric or FlexConnect deployments.

Procedure

1. Enable broadcast packets for wireless clients.

Example

```
Device(config)# wireless broadcast
```

By default, broadcast packets for wireless clients are disabled. When **wireless broadcast** is enabled, broadcast traffic is allowed for each VLAN. Use the **no** form of this command to disable broadcasting packets.

2. Enable broadcast packets for single VLAN.

Example

```
Device(config)# wireless broadcast vlan 3
```

By default, the Broadcast Packets for a Single VLAN feature is disabled. You must enable wireless broadcast to allow broadcasting. Use the **no** form of this command to disable broadcast traffic for each VLAN.

3. Exit the configuration mode.

Example

```
Device(config)# end
```

Configure multicast-over-multicast for AP multicast groups (CLI)

Configure multicast-over-multicast for AP multicast groups using commands.

Enable multicast-over-multicast to optimize client multicast traffic distribution across APs using commands.

Procedure

1. Configure an all-AP multicast group to send a single packet to all the APs.

Example

```
Device(config)# ap capwap multicast 239.4.4.4
```

2. Enable multicast-over-multicast for multicasting client multicast group traffic to all the APs through the underlying all-AP multicast group.

Example

```
Device(config)# wireless multicast 239.4.4.4
```

IP address: Multicast-over-multicast IP address.

3. Exit the configuration mode.

Example

```
Device(config)# end
```

Verify wireless multicast

This section provides verifying wireless multicast details.

- The table provides a comprehensive list of commands for verifying various aspects of wireless multicast, including its general status, IP multicast mode, and mDNS bridging state.

Command	Description
show wireless multicast	Displays the multicast status and IP multicast mode, and each VLAN's broadcast and non-IP multicast status. Also displays the Multicast Domain Name System (mDNS) bridging state.
show wireless multicast group summary	Displays all (Group and VLAN) lists and the corresponding MGID values.
show wireless multicast [**source** *source*] **group** *group* **vlan** *vlanid*	Displays details of the specified (S,G,V) and shows all the clients associated with and their MC2UC status.
show ip igmp snooping wireless mcast-spi-count	Displays statistics of the number of multicast SPIs per MGID sent between IOS and the Wireless Controller Module. feature-id []
	Displays statistics of the number of multicast SPIs per MGID sent internally between IOS and the Wireless Controller Module. feature-id []
show ip igmp snooping wireless mcast-ipc-count	Displays the number of multicast IPCs per MGID sent to the wireless controller module.
show ip igmp snooping wireless mgid	Displays the MGID mappings.
show ip igmp snooping igmpv2-tracking	Displays the client-to-SGV mappings and the SGV-to-client mappings.
show ip igmp snooping querier vlan *vlanid*	Displays the IGMP querier information for the specified VLAN.
show ip igmp snooping querier detail	Displays the detailed IGMP querier information of all the VLANs.
show ipv6 mld snooping querier vlan *vlanid*	Displays the MLD querier information for the specified VLAN.
show ipv6 mld snooping wireless mgid	Displays MGIDs for the IPv6 multicast group.

Multicast optimization

This topic describes multicast optimization details.

Previously, multicast was based on a combination of multicast addresses and VLANs, grouped together as a single entity called MGID. Using the VLAN group can lead to an increase in duplicate packets. When the VLAN group feature is enabled, each client listens to the multicast stream on a different VLAN. As a result, the device creates a separate MGID for each multicast address and VLAN. Consequently, the upstream router sends one copy per VLAN, resulting in a number of copies equal to the number of VLANs in the group. Since all clients use the same WLAN, multiple copies of the multicast packet are sent across the wireless network. The multicast optimization feature suppresses duplication of multicast streams on the wireless medium between the device and the APs.

- This feature enables you to create a multicast VLAN for multicast traffic. You can configure one of the VLANs in the device as a multicast VLAN, where multicast groups are registered. Clients can listen to a multicast stream on the multicast VLAN. The MGID is generated based on the multicast VLAN and multicast IP addresses.

- If multiple clients on different VLANs within the same WLAN listen to a single multicast IP address, the device generates a single MGID. The device ensures that all multicast streams from clients in the VLAN group are sent via the multicast VLAN. This approach allows the upstream router to use a single entry for all VLANs in the VLAN group. Only one multicast stream is sent to the VLAN group, even when clients are on different VLANs. As a result, the device sends only one multicast stream over the network.

Configure IP multicast VLAN for WLAN (GUI)

Configure IP multicast VLAN for WLAN using GUI.

Configure an IP multicast VLAN for a Wireless LAN to enable efficient multicast traffic delivery using the GUI.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **Policy**.
2. Click **Add**.
3. In the **General** tab, enter the **Name** and **Description**.
4. Enable the **Central Switching** and **Central Association** toggle buttons.
5. In the **Access Policies** tab, under the **VLAN** settings, choose the vlans from the **VLAN/VLAN Group** drop-down list and enter the **Multicast VLAN**.
6. Click **Apply to Device**.

Configure IP multicast VLAN for WLAN (CLI)

Configure IP multicast VLAN for WLAN using commands.

Set up IP multicast VLAN for WLAN to enable both IPv4 and IPv6 multicast forwarding to APs using commands.

Before you begin

- This feature is not supported in Fabric or FlexConnect deployments.
- Multicast VLAN is used for both IPv4 and IPv6 multicast forwarding to APs.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy default-policy-profile
   ```

3. Configure central association for locally switched clients.

Example

```
Device(config-wireless-policy)# central association
```

4. Configure WLAN for central switching.

   Example

   ```
   Device(config-wireless-policy)# central switching
   ```

5. Optional: Add a description for the policy profile.

   Example

   ```
   Device(config-wireless-policy)# description test
   ```

6. Assign the profile policy to the VLAN.

   Example

   ```
   Device(config-wireless-policy)# vlan 32
   ```

7. Configure multicast for the VLAN.

   Example

   ```
   Device(config-wireless-policy)# multicast vlan 84
   ```

8. Enable the profile policy.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

Verify the multicast VLAN configuration

Verify the multicast VLAN configuration.

To view the multicast VLAN associated with a policy profile along with the VLAN assigned to that profile, use this command:

```
Device# show wireless profile policy detail default-policy-profile
Policy Profile Name           : default-policy-profile
Description                   : default policy profile
Status                        : ENABLED
VLAN                          : vlan-pool1
                Multicast VLAN : 84
Client count                  : 0
Passive Client                : DISABLED
```

To view the multicast VLAN associated with a client, use this command:

```
Device# show wireless client mac ac2b.6e4b.551e detail
Client MAC Address : ac2b.6e4b.551e
Client IPv4 Address : 192.0.2.20
……….
VLAN : 82
Access VLAN : 82
                Multicast VLAN: 84
```

Multicast filtering

Outlines multicast filtering configuration per WLAN, detailing how the feature selectively controls IGMP and MLD group membership requests for IPv4 and IPv6 clients, prevents unauthorized AP group access, and reviews release support history on Cisco IOS XE.

A multicast filter is a wireless network feature that

- selectively controls the acceptance or dropping of multicast group membership requests from wireless clients
- supports configuration per WLAN for both IPv4 (using IGMP) and IPv6 (using MLD), and
- prevents addition of unauthorized clients to AP multicast groups by filtering protocol-specific reports.

The multicast filtering feature is disabled by default. You can enable or disable the multicast filtering feature per WLAN, from the controller.

You can enable or disable the multicast filtering feature per WLAN from the controller. When you enable this feature, the APs drop the internet group management protocol (IGMP) join request from any client that is part of the WLAN and attempts to join a Layer 3 multicast group address. When you disable this feature, the APs honor the IGMP join request from clients that are part of the WLAN.

This table shows AP behavior for IPv4 and IPv6:

Table 100: Multicast filtering per WLAN

Multicast filtering feature status	IPv4	IPv6
Enabled	AP drops the internet group management protocol (IGMP) membership report from a client that is a part of a WLAN.	AP drops the multicast listener discovery (MLD) report with multicast group address scope value greater than three from a client that is a part of a WLAN.
Disabled	AP honors the IGMP membership report from the client that is a part of a WLAN.	AP honors the MLD report from the client that is a part of a WLAN

Feature history for multicast filtering

- This table provides release and related information for the feature explained in this module.
- This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 101: Feature history for multicast filtering

Feature name	Release information	Feature description
Multicast filtering	Cisco IOS XE 17.3.1	From this release, the multicast filtering feature is supported on Layer 3 for IPv6.
Multicast filtering	Cisco IOS XE 17.2.1	From this release, the multicast filtering feature is supported on Layer 3 for IPv4.

Supported L3 multicast report for filtering

This section provides supported L3 multicast report for filtering details.

APs drop IGMP and MLD join requests from clients on the WLAN for any Layer 3 multicast group address, based on these filtering options:

- IPv4: IGMP versions to be filtered:
  - V1 membership report (0x12)
  - V2 membership report (0x16)
  - V3 membership report (0x22)
- IPv6: ICMPv6 types to be filtered, except link-local multicast packets:
  - Multicast Listener report: MLD Version 1 (131)
  - Multicast Listener report: MLD Version 2 (143)

Note

Filtering supported types prevents creating or adding a client entry to the AP multicast group table.

Configure multicast filtering (CLI)

Use this procedure to configure multicast filtering using commands.

Enable multicast filtering to control the flow of multicast traffic on a specific WLAN using commands.

Perform the procedure given here to create a policy profile and then enable Multicast Filtering on a WLAN:

Procedure

1. Enter the global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a WLAN policy profile and enter the wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy rr-xyz-policy-1
   ```

3. Configure a multicast filter.

   Example

   ```
   Device(config-wireless-policy)#multicast filter
   ```

   Use the **no** form of this command to disable the feature.

What to do next

1. Create a policy tag. For more information about creating policy tags, see *Configuring a Policy Tag (CLI)*.
2. Map the policy tag to an AP. For more information about mapping a policy tag to an AP, see *Attaching a Policy Tag and Site Tag to an AP (CLI)*.

Verify multicast filtering

This section provides verifying multicast filtering details.

To verify if multicast filtering is enabled, use the **show wireless profile policy detailed** *named-policy-profile* command:

```
Device# show wireless profile policy detailed named-policy-profile
Policy Profile Name                : named-policy-profile
Description                        :
Status                             : DISABLED
VLAN                               : 91
Multicast VLAN                     : 0
OSEN client VLAN                   :
Multicast Filter                   : ENABLED
```

97 Map-Server Per-Site Support

Topics:

- Map server per site support

Map server per site support

Explains how map servers per site enable flexible traffic segmentation and virtual network assignments for multiple sites.

A map server per site support is a network feature that

- selects the map server based on the client's subnet to enable per-site segmentation. The controller supports multiple sites and segregates each site's traffic
- allows both Enterprise and Guest sites to use dedicated or shared map servers, and
- enables flexible virtual network assignment using the Layer 2 Virtual Network Identifier (VNID) selection.

This list shows the map server selection order for AP query and client registration:

- Per-L3 VNID map server.
- Per site (ap-group) map server.
- Default or global map server.

Benefits

Some of the benefits of using the map server per site feature are:

- You can use a single large site with horizontal-scaling of the map server and border nodes.
- You can share the controller across multiple sites. Each site can have its own map server and virtual network (VNID), and traffic can still be segmented from each site.
- You can share the guest map server across multiple sites while keeping the enterprise map server separate.
- You can use the same SSID across different sites. Within a site, the SSIDs can belong to different virtual network domains.

Configure the default map server (GUI)

Configure the default map server using GUI.

Set up the default map server to manage control plane operations within the wireless fabric.

Procedure

1. Choose **Configuration** > **Wireless** > **Fabric**.
2. On the **Fabric** page, click the **Control Plane** tab.
3. In the **Control Plane Name** list, click **default-control-plane**.
4. In the **Edit Control Plane** window that is displayed, click **Add**.
5. Enter the IP address of the map server.
6. Set the **Password Type** as either **Unencrypted** or **AES**.
7. Enter the **Pre Shared Key**.
8. Click **Save**.
9. Click **Update & Apply to Device**.

Configure the default map server (CLI)

Configure the default map server using commands.

To configure a wireless fabric control-plane with a specified map server and pre-shared key for LISP control-plane redundancy and secure AP/client join processes.

Before you begin

- The global map server is the default map server that is used for both AP query (when an AP joins) as well as for client registration (when a client joins).
- We recommend that you configure map servers in pairs to ensure redundancy because the LISP control-plane does not support redundancy inherently.
- To share a map server set, create a map server group, which can be shared across site profiles, fabric profiles, Layer 2 and Layer3 VNID, as well with the default map server.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the control plane name.

   Example

   ```
   Device(config)# wireless fabric control-plane control-plane-name test-map
   ```

   If you do not provide a control plane name, the default-control-plane that is auto generated is used.

3. Configure the IP address and the key for the control plane.

   Example

   ```
   Device((config-wireless-cp)# ip address 10.12.13.14 key pre-shared-key secret
   ```

Configure a map server per site (GUI)

Configure a map server per site using GUI.

Configure the primary and backup map server controllers for a specific site using the GUI.

Before you begin
Ensure you have configured an AP Join Profile before setting up the primary and backup controllers.

Procedure

1. Choose **Configuration** > **Tags & Profiles** > **AP Join**.

2. On the **AP Join Profile** page, click the AP Join Profile name.
3. In the **Edit AP Join Profile** window, click the **CAPWAP** tab.
4. In the **High Availability** tab under **Backup Controller Configuration**, check the **Enable Fallback** check box.
5. Enter the primary and secondary controller names and IP addresses.
6. Click **Update & Apply to Device**.

Configure a map server per site (CLI)

Configure a map server per site using commands.

Set up a map server for each site or AP group.

Before you begin

You can configure map server for each site or each AP group. If a map server is not configured for each VNID or subnet, per-site map server is used for AP queries and client registration.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a site tag and enter the site tag configuration mode.

   Example

   ```
   Device(config)# wireless tag site site-tag test-site
   ```

3. Associate a fabric control plane name with a site tag.

   Example

   ```
   Device(config-wireless-site)# fabric control-plane map-server-name test-map
   ```

Create a map server for each VNID (GUI)

Create a map server for each VNID using GUI.

Configure map servers for Layer 2 VNIDs to enable secure fabric communication.

Procedure

1. Choose **Configuration** > **Wireless Plus** > **Fabric** > **Fabric Configuration**.
2. In the **Profiles** tab, click **Add** to add a new Fabric Profile.
3. In the **Add New Profile** window that is displayed, enter a name and description for the profile.

4. Specify the L2 VNID and SGT Tag details.
5. In the **Map Servers** section, specify the IP address and preshared key details for Server 1.
6. Optionally, you can specify the IP address and preshared key details for Server 2.
7. Click **Save & Apply to Device.**

Create a map server for each VNID (CLI)

Create a map server for each VNID using commands.

Follow the procedure given below to configure map server for each VNID in Layer 2 and Layer 3 or a map server for a client VNID.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a map server for each VNID in Layer 2 and Layer 3 or a map server for a client VNID. Use one of the following:

   Example

   ```
   Device(config)# wireless fabric name vnid-map test1 l2-vnid l2-vnid l3-vnid
   l3vnid 10 ip network-ip subnet-mask 10.8.6.2 255.255.255.236 control-plane
   control-plane-name cp1
   ```

   Example

   ```
   Device(config)# wireless fabric name vnid-map test1 l2-vnid l2-vnid
   control-plane control-plane-name cp1
   ```

Create a fabric profile and associate a tag and VNID (GUI)

Create a fabric profile and associate a tag and VNID using GUI.

Use these steps to create a fabric profile in the Cisco wireless GUI and associate it with a tag and VNID.

Procedure

1. Choose **Configuration** > **Wireless** > **Fabric**.
2. In the **Profiles** tab on **Fabric Configuration** page, click **Add** to add a new profile.
3. In the **Add New Profile** window that is displayed, enter a name and description for the profile.
4. Specify the L2 VNID and SGT Tag details.
5. Click **Save & Apply to Device**.

Create a fabric profile and associate a tag and VNID (CLI)

Create a fabric profile and associate a tag and VNID using commands.

Follow the procedure given below to create a fabric profile and associate the VNID to which the client belongs and the SGT tag to this profile.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a fabric profile.

   Example

   ```
   Device(config)# wireless profile fabric fabric-profile-name test-fabric
   ```

3. Configure an SGT tag.

   Example

   ```
   Device(config-wireless-fabric)# sgt-tag value 5
   ```

4. Configure a client Layer 2 VNID.

   Example

   ```
   Device(config-wireless-fabric)# client-l2-vnid vnid 10
   ```

Verify the map server configuration

Verify the map server configuration.

Use the following commands to verify the map server configuration:

```
Device# show wireless fabric summary

Fabric Status      : Enabled

Control-plane:
Name                            IP-address        Key
       Status
-------------------------------------------------------------------------------------
test-map                        10.12.13.14       test1
       Down

Fabric VNID Mapping:
```

```
  Name               L2-VNID        L3-VNID        IP Address
Subnet        Control plane name
------------------------------------------------------------------------------

  test1               12             10             10.6.8.9
255.255.255.236    test2
```

```
Device# show wireless fabric vnid mapping

Fabric VNID Mapping:
  Name               L2-VNID        L3-VNID        IP Address
Subnet      Control Plane Name
------------------------------------------------------------------------------

  fabric1             1              0              9.6.51.0
255.255.255.0          map-server-name
```

```
Device# show wireless profile fabric detailed profile-name

Profile-name      : fabric-ap
VNID              : 1
SGT               : 500
Type              : Guest

Control Plane Name       Control-Plane IP   Control-Plane Key
------------------------------------------------------------------------------

 Ent-map-server           5.4.3.2                guest_1
```

```
Device# show ap name ap-name config general

Fabric status                                  : Enabled
RLOC                                           : 2.2.2.2
Control Plane Name  : ent-map-server
```

```
Device# show wireless client mac mac-address detail

Fabric status : Enabled
RLOC                   : 2.2.2.2
Control Plane Name  : ent-map-server
```

```
Device# show wireless tag site detailed site-tag

Site Tag Name        : default-site-tag
Description          : default site tag
---------------------------------------
AP Profile           : default-ap-profile
Local-site           : Yes
Fabric-control-plane: Ent-map-server
```

98 Volume Metering

Topics:

- Volume metering

Describes how to configure AP reporting intervals and controller accounting updates so administrators can reduce latency in client usage reporting and forward interim accounting data to a RADIUS server.

Volume metering

Introduces Volume Metering principles and provides instructions for configuring volume metering using detailed tasks, guiding users through the setup and implementation process for monitoring network traffic volume.

A volume metering feature is an access point data reporting capability that

- allows you to set the interval for client accounting statistics updates from the access point (AP) to the network controller,
- supports configurable reporting frequencies from five to 90 seconds, and
- helps minimize delays in updating usage data for connected devices.

Additional information

By default, the access point sends client accounting updates to the controller every 90 seconds, which then forwards this information to the RADIUS server. With volume metering features, you can adjust the reporting interval from five seconds to 90 seconds.

This flexibility enables network administrators to better control the timeliness of usage data, ensuring more immediate reporting and improved network accounting accuracy.

Example

If you want to decrease the delay in receiving accounting data for a device, you can configure the reporting interval to 10 seconds so that the access point sends updates to the controller—and subsequently to the RADIUS server—much more frequently than the default 90 seconds.

This supports more accurate, real-time accounting of network usage.

Configure volume metering (CLI)

Use this procedure to configure volume metering on your device. This task helps you set the reporting intervals for 2.4 GHz and 5 GHz radios and configure accounting updates for client sessions.

Configure device parameters to control how often the system reports wireless usage data and sends accounting updates to the Remote Authentication Dial-In User Service (RADIUS) server.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an access point (AP) profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile profile-name
   ```

3. Configure the 2.4 GHz (802.11ax) reporting interval.

Example

```
Device(config-ap-profile)# dot11 24ghz reporting-interval reporting-interval
```

4. Configure the 5 GHz (802.11ax) reporting interval.

   Example

   ```
   Device(config-ap-profile)# dot11 5ghz reporting-interval reporting-interval
   ```

5. Return to global configuration mode.

   Example

   ```
   Device(config-ap-profile)# exit
   ```

6. Set the time interval (in minutes) at which the controller sends interim accounting updates for the client to the RADIUS server.

   Example

   ```
   Device(config)# aaa accounting update periodic interval-in-minutes
   ```

7. Exit configuration mode and return to privileged EXEC mode.

   Example

   ```
   Device(config)# exit
   ```

The device reports volume metering data at your specified intervals and sends accounting updates to the RADIUS server.

99 Enabling Syslog Messages in Access Points and Controller for Syslog Server

Topics:

- Syslog messages in access points and controllers
- AP logging to the in-memory buffer and flash

Explains how to configure syslog messaging on access points and controllers, including setup for syslog servers and logging to in-memory buffers and flash storage.

Syslog messages in access points and controllers

Introduces syslog messaging concepts for access points and controllers, detailing client state change support, configuration procedures via CLI and GUI, sample syslog formats, and syslog server setup instructions.

A syslog message in access points and controllers is a log communication that

- captures and records operational events generated by each device
- is routed to various destinations, including memory buffers, terminal sessions, device storage, or external syslog servers, and
- allows administrators to configure logging independently on access points and controllers to meet specific network requirements.

Configuring message logging in the IOS XE controller

System Message Logging in Cisco Catalyst 9800 Series Controllers is a platform-independent IOS and IOS XE feature. For more details, see:

- System Message Logging
- Configuration Logger Persistency chapter in *System Management Configuration Guide*
- Logging to Local Nonvolatile Storage chapter in *System Management Configuration Guide*
- Embedded Syslog Manager (ESM) chapter in *System Management Configuration Guide*
- Configuration Change Notification and Logging chapter in *System Management Configuration Guide*

Syslog support for client state change

This concept explains how syslog client state change events track critical transitions in wireless client connectivity, including the data captured and expected behavior when the feature is enabled.

A syslog client state change event is a network monitoring mechanism that

- records when a wireless client joins, obtains a new IP address, or disconnects from the network,
- captures details such as client IP addresses and access point (AP) names to support network monitoring, and
- provides actionable event logs for operational troubleshooting.

Feature details

A syslog event is generated in these situations:

- When a client enters the RUN state,
- when a client receives a new IP address (IPv4 or IPv6) in the RUN state, and
- when a client in the RUN state is deleted.

> **Note**
>
> If syslog support for client state change is enabled and an access point (AP) transitions from standalone to connected, usernames may temporarily appear as null in syslog messages and in client details for 802.1X clients associated with that AP.
>
> This behavior does not affect operations. The system updates usernames automatically after about 30 seconds.

For more information about the IOS XE Controller, see System Message Logging.

Example: Syslog Support for Client State Change

For example, when a client joins a wireless network and obtains a new IP address, a syslog message is generated to record the event, including details such as the client's IP address and the associated AP name.

Configure syslog support for client state change (CLI)

Learn how to configure syslog support for client state change using CLI commands.

Enable the system to log detailed client state changes for monitoring and troubleshooting.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable detailed syslogs for client events.

   Example

   ```
   Device(config)# wireless client syslog-detailed
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device logs detailed syslog messages whenever a client state changes, aiding in network monitoring and troubleshooting.

Sample syslogs

Sample syslogs details.

802.11x authentication

This example shows a client IP update:

```
Oct  1 14:41:27.785 IST: %CLIENT_ORCH_LOG-7-CLIENT_IP_UPDATED:
Chassis 1 R0/0: wncd: Username (dev2), MAC: 0062.xxxx.0077,
IP fe80::262:aff:xxxx:77 101.6.2.119 2001:300:8:0:362:aff:xxxx:77
2001:300:8:0:762:aff:xxxx:77
2001:300:8:0:562:aff:xxxx:77 2001:300:8:0:962:aff:xxxx:77
2001:300:8:0:462:aff:xxxx:77
IP address updated, associated to AP (Asim_06-11) with SSID (dev_abcd_wlan_1)
```

This example shows a client RUN state:

```
Oct  1 14:41:27.779 IST: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_RUN_STATE:
Chassis 1 R0/0: wncd: Username (dev2), MAC: 0062.xxxx.006a, IP 101.xxxx.2.106
 associated to AP
(Asim_06-10) with SSID (dev_abcd_wlan_1)
```

Open authentication

This example shows a client IP update:

```
Sep 18 03:22:35.902: %CLIENT_ORCH_LOG-7-CLIENT_IP_UPDATED:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP 9.9.xxxx.252
fe80::643c:87c1:xxxx:c1c4 IP address updated,
associated to AP (AP2C5A.xxxx.159A) with SSID (test1)
```

This example shows a client RUN state:

```
Sep 18 03:22:35.257: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_RUN_STATE:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP 9.9.xxxx.252
associated to AP (AP2C5A.xxxx.159A) with SSID (test1)
```

This example shows a client delete state:

```
Sep 18 03:24:45.083: %CLIENT_ORCH_LOG-7-CLIENT_MOVED_TO_DELETE_STATE:
Chassis 1 R0/0: wncd: Username (null), MAC: 6014.xxxx.c5fb, IP
fe80::643c:xxxx:e316:c1c4 2001:300:42:0:643c:87c1:xxxx:c1c4
2001:300:42:0:xxxx:82ce:1ae4:5a32 9.9.xxxx.252 disconnected from AP
(AP2C5A.xxxx.159A) with SSID (test1)
```

Configure the syslog server for the controller (GUI)

Use this procedure to configure a syslog server for controller log management using the GUI.

Enable centralized log management by forwarding controller system logs to a designated syslog server through the controller GUI.

Procedure

1. Choose **Troubleshooting** > **Logs**.

2. Click **Manage Syslog Servers**.
3. In **Log Level Settings**, from the **Syslog** drop-down list, choose a severity level.
4. From the **Message Console** drop-down list, choose a logging level.
5. In **Message Buffer Configuration**, from the **Level** drop-down list, choose a server logging level.
6. In **Size (bytes)**, enter the buffer size. The value can range from 4,096 to 2,147,483,647.
7. In **IP Configuration** settings, click **Add**.
8. From the **Server Type** drop-down list, choose **IPv4**, **IPv6**, or **FQDN**.
9. If you choose **IPv4** or **IPv6**, enter the **Server Address**. If you choose **FQDN**, enter the **Host Name**. Then choose the IP type and the appropriate **VRF Name** from the drop-down lists.

   To delete a syslog server, click **x** next to the appropriate server entry under the **Remove** column.

   > **Note**
   >
   > Spaces are not allowed in the host name.

10. Click **Apply to Device**.

    > **Note**
    >
    > When you click **Apply to Device**, the system applies the changes. If you click **Cancel**, the system discards the changes.

After you apply the configuration, log messages are forwarded to the specified syslog server.

Configure a syslog server for a controller (CLI)

Use this procedure to configure a syslog server for an embedded-wireless controller using CLI commands to enable centralized logging and monitoring for auditing and troubleshooting.

Configure the controller to send system and event messages to a remote syslog server for monitoring.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enter the syslog server IP address and configure its parameters.

   Example

   ```
   Device(config)# logging hostname ipv6
   ```

3. Enable the facility parameter for syslog messages.

   Example

   ```
   Device(config)# logging facility {auth | cron | daemon | kern | local0 |
   local1 | local2 | local3 | local4 | local5 | local6 | local7 | lpr | mail |
   news | sys10 | sys11 | sys12 | sys13 | sys14 | sys9 | syslog | user | uucp}
   ```

   Example

   ```
   Device(config)# logging facility syslog
   ```

   You can enable these facility parameters for syslog messages:

   - **auth** Authorization system.
   - **cron** Cron facility.
   - **daemon** System daemons.
   - **kern** Kernel.
   - **local0** to **local7** Local use.
   - **lpr** Line printer system.
   - **mail** Mail system.
   - **news** USENET news.
   - **sys10** to **sys14** and **sys9** System use.
   - **syslog** Syslog itself.
   - **user** User process.
   - **uucp** Unix-to-Unix copy system.

4. Set the logging level for the syslog server.

   Example

   ```
   Device(config)# logging trap {severity-level | alerts | critical | debugging
    | emergencies | errors | informational | notifications | warnings}
   ```

   Example

   ```
   Device(config)# logging trap 2
   ```

   severity-level Refers to the logging severity level. The valid range is from zero to seven.

   These are the syslog server logging levels:

   - **emergencies** Signifies severity 0. The system is not usable.
   - **alerts** Signifies severity 1. Immediate action is required.
   - **critical** Signifies severity 2. Critical conditions.
   - **errors** Signifies severity 3. Error conditions.

- **warnings** Signifies severity 4. Warning conditions.
- **notifications** Signifies severity 5. Normal but significant conditions.
- **informational** Signifies severity 6. Informational messages.
- **debugging** Signifies severity 7. Debugging messages.

> **Note**
>
> Select a syslog level to view the supported levels. Selecting a level also enables all lower levels.
>
> If you enable the *critical* syslog level, the system also enables lower levels–*alerts* and *emergencies*.

5. Enter privileged EXEC mode.

Example

```
Device(config)# end
```

Alternatively, press **Ctrl-Z** to exit global configuration mode.

The controller now forwards syslog messages to the specified syslog server as configured.

AP logging to the in-memory buffer and flash

Describes access point logging capabilities to in-memory buffers and flash storage, covering terminal logging, syslog server configuration for AP profiles, GUI-based syslog settings, and verification commands.

AP always log messages to an in-memory buffer. Once the buffer reaches 40 KB, its contents are automatically written to flash memory, and a new buffer is created.

Administrators can manage and view these logs using AP commands.

- **show logging** command to display the contents of the in-memory logging buffer
- **show flash syslogs** command to list all log files stored in flash, along with other diagnostic files
- **<filename>** command to display the contents of an individual log file stored in flash
- **copy syslogs <filename>** command to transfer a specific syslog file to an external server. To see available options for this command, use **copy syslogs <filename>**

AP logging to terminal

This topic explains how access points support real-time logging of messages to an active SSH terminal session and the use of the terminal monitor command for enabling or disabling this feature.

Access points support real-time logging of messages to an active SSH terminal session, which can be enabled or disabled using the **terminal monitor** and **terminal monitor disable** commands.

Administrators can enable real-time logging to an SSH terminal session using the **terminal monitor** command. To disable real-time logging to the session, use the **terminal monitor disable** command. In addition to SSH terminal sessions, APs send a subset of log messages to the serial console, providing another method for real-time monitoring.

Configure AP logging to a syslog server

This topic explains how to configure access point (AP) syslog logging, including setting the syslog host, filtering messages by severity and facility, enabling secure transmission, and viewing current syslog settings.

Use the **syslog** command in the AP join profile to configure the destination IP address for syslog messages and manage which messages are sent based on severity and facility levels.

Configure the syslog host

- Use the **syslog host <IP address>** command to specify the destination IP address for syslog messages.
- By default, the syslog host is **255.255.255.255** , the IPv4 limited broadcast address.
- Configure IP helper addresses on the AP subnet router to forward broadcasts to one or more syslog servers.
- To reset the syslog host to **255.255.255.255** , use either the **default syslog host** or **no syslog host** command.
- To prevent the AP from sending syslog messages entirely, use **syslog host 0.0.0.0** .
- If a subnet contains more than 20 access points, do not log to the broadcast address. This prevents flooding the broadcast domain with log messages. Configure a specific syslog destination IP address.
- If you do not use the AP syslog feature, set the syslog host to **0.0.0.0** by entering the **syslog host 0.0.0.0** command.

Filter messages by severity

- Use the **syslog level <levelname>** command to filter messages based on severity.
- By default, the severity level is **informational** (**severity=6**), which means the system sends all messages except debugging logs to the server.

Filter messages by facility

- Use the **syslog facility <facilityname>** command to filter messages based on the facility code (facility name).
- By default, the facility is **kernel** (**kern** , **code=0**), so the system sends only kernel-related messages.
- To send messages from all facilities, configure the facility as **local7** .
- The configured facility name is included in the facility field of transmitted syslog messages.

> **Note**
>
> Most AP log messages use the **kern** facility, while terminal access logs such as SSH and console access use the **auth** facility.

Secured syslog transmission

- Use the **syslog secured** command to enable Transport Layer Security (TLS), as defined in RFC 5425, to transmit syslog messages securely instead of using UDP.

- TLS-based syslog transmission is supported starting with software versions 17.9.6 and 17.12.1 (released in June 2023 and December 2023, respectively).

View syslog settings

To display the current syslog settings for an AP, use the **show capwap client configuration** command.

Configure a syslog server for an AP profile (CLI)

Learn how to configure a syslog server for an AP profile using CLI commands.

Configure a syslog server for an AP profile.

This ensures access points send system log messages to a specified remote server for central monitoring and troubleshooting.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile. Then, enter the AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

3. Configure the facility parameter used by syslog messages.

   Example

   ```
   Device(config-ap-profile)# syslog facility
   ```

4. Enter the Syslog server IP address and parameters to define where the AP profile sends log messages.

   Example

   ```
   Device(config-ap-profile)# syslog host ip-address
   ```

5. Set the syslog server logging level to determine which messages the AP profile sends.

   Example

   ```
   Device(config-ap-profile)# syslog level {alerts | critical | debugging |
   emergencies | errors | informational | notifications | warnings}
   ```

   Example

   ```
   Device(config-ap-profile)# syslog level
   ```

   The syslog server supports these logging levels:

- **emergencies** –Signifies severity 0. Indicates that the system is not usable.
- **alerts** –Signifies severity 1. Indicates that an immediate action is required.
- **critical** –Signifies severity 2. Indicates a critical condition.
- **errors** –Signifies severity 3. Indicates an error condition.
- **warnings** –Signifies severity 4. Indicates a warning condition.
- **notifications** –Signifies severity 5. Indicates normal, but significant, conditions.
- **informational** –Signifies severity 6. Indicates informational messages.
- **debugging** –Signifies severity 7. Indicates debugging messages.

> **Note**
>
> Select a syslog level to enable it and all lower levels.
>
> If you enable the *critical* syslog level, *alerts* and *emergencies* are also enabled.

6. Return to privileged EXEC mode.

Example

```
Device(config-ap-profile)# end
```

Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The syslog server is configured for the specified AP profile. APs that use this profile will send log messages with the selected severity levels to the designated remote server.

Configure the AP syslog settings (GUI)

Learn how to configure syslog settings on access points (APs) using the GUI to control log destination, facility, and security options.

Set up syslog parameters for access points. This enables monitoring and centralized logging of events.

Procedure

---

1. Choose **Configuration**, then **Tags and Profiles**, then **AP Join**.
2. Select the APs from the AP list.

   The **Edit AP Join Profile** window is displayed.
3. Click the **Management** tab.
4. Select the **Device** tab.
5. In the **System Log** section:
   a) From the **Facility Value** drop-down list, select a value.
   b) Enter the IP address in the **Host IPv4 or IPv6 Address** field.

c) From the **Log Trap Value** drop-down list, select a value.
d) To enable **Secured**, check the box. To disable **Secured**, clear the box.

6. Click **Update and Apply to Device**

The selected APs are updated with the new syslog configuration, enabling centralized logging according to your specified parameters.

Verify syslog server configurations

Verify Syslog Server Configurations.

Verify global syslog server settings for all APs

To view the global syslog server settings for all access points that joins the controller, use this command:

```
Device# show ap config general
Cisco AP Name : APA0F8.4984.5E48

100 Login Banner

Topics:

- Login banners

This chapter explains how to configure customizable login banners on the controller via GUI or CLI, including delimiter rules, examples, verification, and saving steps, so administrators can display legal notices or security warnings before user authentication.

Login banners

This concept explains the purpose, configuration requirements, and known limitations of login banners in controller systems.

A login banner is a user authentication feature that

- displays a customizable warning or informational message when you attempt to access the controller
- uses a delimiting character to mark the start and end of the banner text, and
- helps communicate security policies or legal notices to users before granting access.

Additional reference information

To configure a login banner, you must specify a delimiting character that signals the system to treat the enclosed text as the banner message. After entering the delimiting character, enter the message text, and then repeat the same character at the end.

The delimiter can be any single character from the extended ASCII set, but that character cannot appear inside the banner message once selected as the delimiter.

For example, to create a login banner with the delimiter `#`, enter:

```
banner login #Unauthorized access is prohibited#
```

Note

When HTTP authentication is configured using TACACS+ or RADIUS, the banner message does not display on the Web UI. (Addressed CSCvr26813: C9800 - Banner not seen on GUI with TACACS authentication.)

Configure a login banner (GUI)

Use this procedure to configure a login banner using the web-based GUI. This enables you to display a customized message to users prior to device login.

Set up a custom login banner to communicate important information or legal notices to users before they access the device.

Procedure

1. Choose **Administration** > **Device** .
2. In the **General** tab, in the **Banner** field, enter a name for the device and a message.
3. Click **Apply** .

The customized login banner is displayed to users before they authenticate to the device.

Configure a login banner (CLI)

Learn how to configure a login banner to display a custom message when users log in to a device.

Set a login banner to inform users about security policies or authorized access.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   If prompted, enter your password.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Specify the login message.

   Example

   ```
   Device(config)# banner login c message c
   ```

   Example

   ```
   Device(config)# banner login $
   Access for authorized users only.
   Please enter your username and password.
   $
   ```

   - c: Enter the delimiting character of your choice (for example, the pound sign), then press the **Return** key. The delimiting character marks the beginning and end of the banner text. Any characters after the ending delimiter are discarded.
   - Message: Enter a login message up to 255 characters. The delimiting character cannot be used in the message.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

5. Verify your entries.

   Example

   ```
   Device# show running-config
   ```

6. Optional: Save your entries to the configuration file.

   Example

   ```
   Device# copy running-config startup-config
   ```

All users see the login banner when they attempt to log in.

101 Wi-Fi Alliance Agile Multiband

Topics:

- Wi-Fi alliance agile multiband

Introduces the WiFi Alliance Agile Multiband standard and explains its role in optimizing wireless network performance across multiple frequency bands.

Wi-Fi alliance agile multiband

Introduces WiFi Alliance Agile Multiband technology, detailing topology components, supported MBO components, limitations, WLAN configuration procedures, and verification methods for optimizing multiband wireless networks.

A Wi-Fi alliance agile multiband feature is a Wi-Fi interoperability certification that

- enables better use of Wi-Fi network resources by leveraging information from both networks and clients,
- certifies features defined by the IEEE 802.11k, 802.11v, and 802.11u amendments and Wi-Fi Alliance specifications, and
- improves Wi-Fi client roaming decisions and the overall network user experience.

- MBO certified clients: Devices that comply with Wi-Fi alliance testing for agile multiband interoperability.
- IEEE 802.11k, 802.11v, and 802.11u amendments: Standards that provide networks and clients with mechanisms to exchange information about network topology, quality, and roaming policies.
- RF neighbors: Other radio devices in the vicinity that could affect Wi-Fi performance, as detected and reported by access points (APs) or clients.

Additional reference information

The Wi-Fi alliance agile multiband (MBO) feature enables better use of Wi-Fi network resources. Wi-Fi networks and client devices share information to improve roaming decisions and overall Wi-Fi performance.

> **Note**
>
> This feature applies only to MBO certified clients.

This feature certifies the interoperability of features defined by the IEEE 802.11k, 802.11v, and 802.11u amendments, as well as Wi-Fi Alliance specifications. These technologies are used to exchange access point (AP) information such as band and channel preferences, link quality, and status information between an AP and a client device.

MBO focuses on the following:

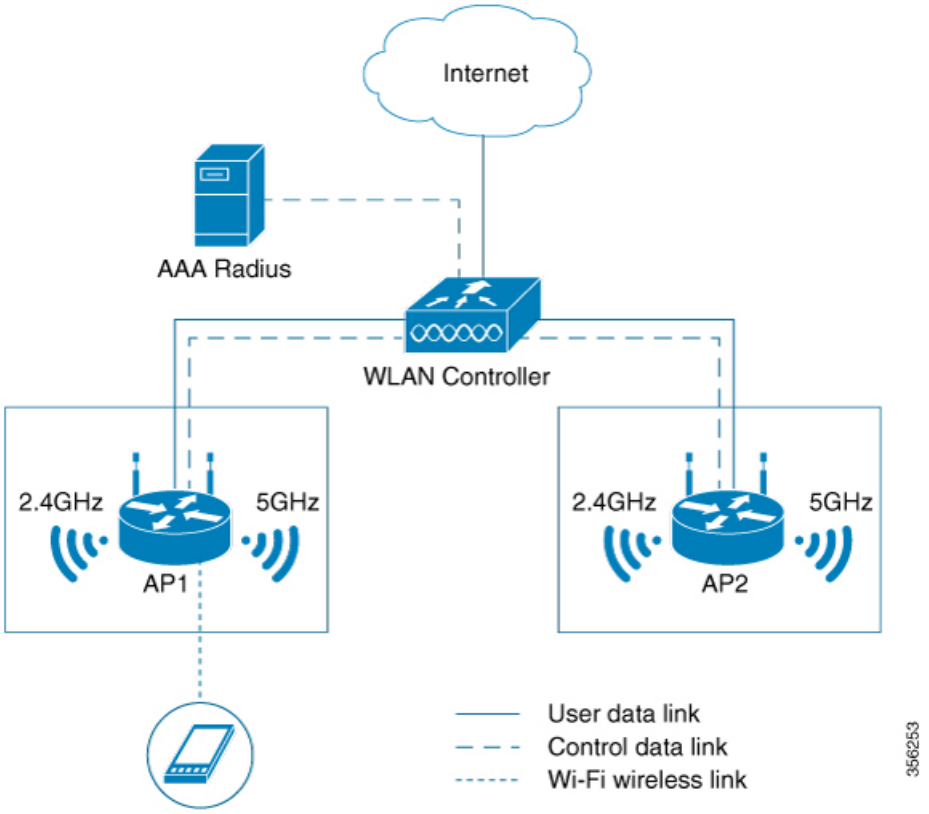
- Interactions between wireless clients and APs,
- Exchange of information between APs and clients about the wireless medium (such as RF neighbors), and
- Allowing clients to work with APs to make intelligent connection decisions and improve quality of service.

Example of MBO in Action

For example, when a client device supports MBO, it can receive information from multiple APs about available channels and link quality. This information enables the client to select the best AP for optimal performance and seamless roaming.

Components of a Wi-Fi Agile Multiband topology

This section lists the main components and roles within a Wi-Fi Agile Multiband wireless infrastructure network.



This topic describes the system topology and components involved in a Wi-Fi Agile Multiband wireless infrastructure network.

A Wi-Fi Agile Multiband wireless infrastructure network includes these components:

- Access Point (AP): A Wi-Fi Agile Multiband wireless infrastructure network contains one or more Wi-Fi Agile Multiband APs.
- WLAN Controller: A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more WLAN controllers that provide centralized management and other features to the interconnected APs.
- Client Station (STA): A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more Client Stations (STAs). Client Stations support only one WLAN.
- RADIUS Server: A Wi-Fi Agile Multiband wireless infrastructure network contains zero or more RADIUS Servers that provide Authentication, Authorization, and Accounting (AAA) services.

The topology may vary according to deployment requirements.

Figure 9: Wi-Fi agile multiband wireless infrastructure network

Supported MBO components

This section lists the wireless features, requirements, and behaviors supported and not supported by MBO (Multi Band Operation) components on Cisco access points.

This section provides a comprehensive summary of the features, standards, requirements, and behaviors supported by Multi Band Operation (MBO) components on Cisco access points. It enables you to determine compatibility and operational prerequisites for MBO functionality.

MBO AP capability

802.11ax access points add a new information element to the Beacon, Probe Response, Association Response, and Re Association Response frames to indicate MBO support.

> **Note**
>
> The new information element indicates that Cisco access points are not aware of cellular data status.

The MBO AP capability is enabled when an SSID is configured on the access point.

802.11k/v/r support

To support MBO, access points must support 802.11k, 802.11v, and 802.11r standard-based technologies. Each technology has specific requirements:

- 802.11k – The access point sends a list of preferred neighboring access points to the client upon request. It also sends a beacon request when a beacon report is required.
- 802.11v – The access point steers the client to a less congested access point using BSS transition. The target access point must not be in the non-preferred or non-operable channel list sent by the MBO client during the association or WNM notification request.
- 802.11r – MBO-related 802.11r capabilities are not supported.

802.11u ANQP or GAS support

For MBO, 802.11ax access points must support 802.11u ANQP or GAS.

These are the prerequisites:

- The access point responds to the ANQP request for a neighbor report ANQP element.
- Before authentication, the network must provide Layer 2 transport between the mobile device and the server to support advertisement protocol frames.

MBO beacon request

When an access point sends a beacon request to the client, an MBO-compliant client responds with a beacon report.

MBO associate disallowed IE

When Cisco access points cannot accommodate new clients, they include an **Associate Disallowed IE** in the Beacon, Probe Response, or (Re) Association Response.

Limitations of MBO

Understand the limitations while using MBO. Use these guidelines when evaluating access point compatibility with MBO features.

Only 802.11ax access points are supported.

Configure MBO on a WLAN (CLI)

Learn how to configure MBO on a WLAN using CLI commands.

Enable Mobility Optimization (MBO) on a WLAN using command-line interface commands to improve client management and network performance.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure a WLAN and enter the WLAN configuration mode.

   Example

   ```
   Device(config)# wlan wlan-name wlan-id ssid
   ```

   Example

   ```
   Device(config)# wlan wlan-demo 1 ssid-demo
   ```

   Note

   If you use WPA2 WLAN while configuring MBO for WLAN, you need to enable PMF in your configuration.

3. Configure MBO support on WLAN.

   Example

   ```
   Device(config-wlan)# mbo
   ```

   Note

   Use the **no mbo** command to disable MBO configuration.

4. Return to privileged EXEC mode.

   Example

   ```
   Device(config-wlan)# end
   ```

   Alternatively, you can also press **Ctrl-Z** to exit global configuration mode.

The WLAN is configured with MBO support. Wireless clients can now benefit from enhanced roaming and optimization features.

Verify MBO configuration

Verify MBO Configuration.

To view the MBO configuration, use this command:

```
Device# show wlan id 1
WLAN Profile Name     : wlan-demo
=================================================
Identifier                                       : 1
Description                                      :
Network Name (SSID)                              : ssid-demo
Status                                           : Disabled

102 SNMP Traps

Topics:

- SNMP trap configuration

This chapter explains how to configure and verify SNMP trap notifications for wireless components (APs, clients, mesh, RF, rogue, mobility, and RRM) using GUI and CLI, including trapflags and host settings.

SNMP trap configuration

Explains SNMP wireless trap functionality and outlines configuration procedures for enabling traps via GUI and CLI, including access points, wireless client, mesh, RF, rogue, mobility, RRM, and general traps, with instructions for verification.

An SNMP trap is an alert message sent from SNMP-enabled devices to an SNMP manager. It does not require acknowledgment from the receiver and does not confirm receipt at the sender.

SNMP trap configuration details

To configure the controller to send SNMP notifications, you must enter at least one **snmp-server host** command. If you do not enter an **snmp-server host** command, the system does not send any notifications.

- To enable multiple hosts, specify a separate **snmp-server host** command for each host.
- You can specify multiple notification types in the command for each host.
- If you issue multiple **snmp-server host** commands for the same host and notification type (trap or inform), each new command overwrites the previous one. The system considers only the most recent **snmp-server host** command.
- For example, entering an **snmp-server host** inform command for a host and then entering another for the same host causes the second command to replace the first.

To specify which SNMP notifications are sent globally, use the **snmp-server enable traps wireless <TrapName>** command. For a host to receive wireless notifications, at least one **snmp-server enable traps wireless <TrapName>** command and the **snmp-server host** command for that host must be enabled.

- Some notification types cannot be controlled with the **snmp-server enable** command.
- Some notification types are enabled by default. For example, a few Access Point (AP)-related traps such as **crash**, **register**, and **noradiocards** are enabled by default.

> **Note**
>
> On physical Cisco Catalyst 9800 Series Wireless Controller appliances, such as Cisco Catalyst 9800-L, 9800-40, and 9800-80, the SNMP trap rate is limited to 4 traps per second. On virtual Catalyst 9800 appliances, the SNMP trap rate supports up to 300 traps per second.

Configure SNMP Traps (GUI)

Configure SNMP traps by using the GUI.

Enable and customize Simple Network Management Protocol (SNMP) trap notifications for wireless events by using the GUI.

Procedure

1. Choose **Administration** > **Management** > **SNMP**.

   The SNMP page appears. By default, SNMP mode is disabled.

   Click the **SNMP Mode** toggle button to enable or disable SNMP.

2. Choose the **Wireless Traps** tab.

By default, only the **Access Point** trap is enabled; all other SNMP wireless traps are disabled.

To enable all wireless traps, click **Enable All**.

3. Select wireless SNMP traps. Select the wireless SNMP trap to enable. Click the **Select All** check box to enable all trap flags in the trap. To enable all trap flags in the **Mesh** trap section, check the **Select All** check box in the section. Clear the **Select All** check box to deselect all trap flags.

   Note

   In the **Access Point** trap, the **Crash**, **No Radio Cards**, and **Register** trap flags are enabled by default. Select the **Broken Antenna** trap flag to detect a broken antenna. Select the **AP Stats** trap flag to enable traps for access point statistics.

4. Click **Apply**.

By configuring SNMP trap notifications, network management systems receive wireless event alerts based on your selections.

Enable AP Traps (CLI)

Enable AP traps with CLI commands.

Configure Simple Network Management Protocol (SNMP) traps on your device to monitor wireless access point (AP) events.

This configuration helps you monitor AP status and troubleshoot issues.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable wireless SNMP traps for APs.

   Example

   ```
   Device# snmp-server enable traps wireless AP
   ```

3. Enable or disable AP-related trap flags.

   Example

   ```
   Device# trapflags ap authorization
   ```

   Example

   ```
   Device# trapflags ap authorization broken-antenna crash interfaceup
   ipaddrfallback mfp mode noradiocards register
   ```

The **crash**, **noradiocards**, and **register** trap flags are enabled by default.

Your device sends SNMP traps for wireless AP events.

This configuration helps you monitor AP status and identify issues.

Enable wireless client traps (CLI)

Enable wireless client traps by using CLI commands.

Configure Simple Network Management Protocol (SNMP) traps on your device to monitor wireless client events. This setup helps you manage and troubleshoot your network.

Procedure

---

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable wireless client traps.

   Example

   ```
   Device# snmp-server enable traps wireless bsnMobileStation
   ```

3. Enable or disable 802.11ax-related trap flags for wireless clients.

   Example

   ```
   Device# trapflags client dot11 assocfail
   ```

   Example

   ```
   trapflags client dot11 assocfail associate authenticate authfail deauthenticate
    disassociate
   ```

4. Enable trap flags that are excluded for clients.

   Example

   ```
   Device# trapflags client excluded
   ```

Your device generates SNMP traps for wireless client events. Your network monitoring tools receive and process these notifications.

Enable Mesh Traps (CLI)

Enable mesh traps with CLI commands.

You can configure a device to send wireless-mesh Simple Network Management Protocol (SNMP) traps and control mesh trap notifications.

Before you begin

To enable mesh traps with CLI commands, complete each step in order.

Procedure

1. Enter the global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable wireless-mesh traps.

   Example

   ```
   Device# snmp-server enable traps wireless MESH
   ```

3. Enable or disable mesh trap flags.

   Example

   ```
   Device# trapflags mesh abate-snr
   ```

   Example

   ```
   trapflags mesh abate-snr authentication-failure child-moved excessive-children
    excessive-hopcount onset-snr parent-change
   ```

The device sends wireless-mesh SNMP traps according to the mesh trap flags you selected.

Enable RF Traps (CLI)

Enable RF traps using commands.

You can configure your device to send radio frequency (RF) traps for wireless networking events using CLI commands.

Before you begin

To enable radio frequency (RF) traps using CLI commands, complete the steps below.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Enable wireless RF-related traps.

Example

```
Device# snmp-server enable traps wireless bsnAutoRF
```

3. Enable or disable sending traps related to radio resource management (RRM) parameter updates.

Example

```
Device# trapflags rrm-params channels tx-power
```

4. Enable or disable traps related to the radio resource management (RRM) profile.

Example

```
Device# trapflags rrm-profile coverage
```

Example

```
trapflags rrm-profile coverage interference load noise
```

The device sends RF-related SNMP traps to support network monitoring of wireless events.

Enable rogue, mobility, RRM, and general traps (CLI)

Enable rogue, mobility, RRM, and general traps using commands.

Configure SNMP traps for wireless rogue devices, mobility events, Radio Resource Management (RRM), and general controller events on your device using the CLI.

Before you begin

Use these steps to enable rogue, mobility, RRM, and general traps.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Enable traps for wireless rogue.

Example

```
Device# snmp-server enable traps wireless rogue
```

3. Enable rogue AP detection trapflag.

Example

```
Device# trapflags rogue-ap
```

4. Enable rogue client detection trapflag.

   Example

   ```
   Device# trapflags rogue-client
   ```

5. Enable traps for wireless mobility.

   Example

   ```
   Device# snmp-server enable traps wireless wireless_mobility
   ```

6. Enable anchor trapflags.

   Example

   ```
   Device# trapflags anchor
   ```

7. Enable traps for wireless RRM.

   Example

   ```
   Device# snmp-server enable traps wireless RRM
   ```

8. Enable or disable the RRM parameter related traps, when the RF manager group changes.

   Example

   ```
   Device# trapflags rrm-params group
   ```

9. Enable general controller traps.

   Example

   ```
   Device# snmp-server enable traps wireless bsnGeneral
   ```

SNMP trap notifications for rogue, mobility, RRM, and general controller events are enabled on the device and will be sent to your configured SNMP management system.

Verify SNMP wireless traps

Verify SNMP Wireless Traps.

To verify the various SNMP traps enabled, use this command:

```
Device# show run | sec trapflag
trapflags ap crash
trapflags ap noradiocards
trapflags ap register
trapflags rogue-client
```

103 Disabling Clients with Random MAC Address

Topics:

- Random MAC addresses

This chapter explains how to configure a Cisco wireless controller to block clients using locally administered (random) MAC addresses: CLI steps to enable/disable the feature, verification commands, and expected outputs.

Random MAC addresses

This concept explains how wireless clients use random (locally administered) MAC addresses, why they improve privacy, and how Cisco controllers control their use within networks.

A random MAC address is a locally administered hardware address that

- is generated by a device (instead of assigned by the manufacturer),
- helps protect user privacy by making device tracking more difficult, and
- can be permitted or denied on wireless networks through controller settings.

Random MAC address denial

Wireless clients traditionally use manufacturer-assigned, globally unique MAC addresses (burn-in addresses) for network association. Devices may also use locally administered, random MAC addresses for Wi-Fi operations to improve privacy. Network administrators can deny access to these clients using this feature.

Beginning with Cisco IOS XE 17.5.1, access controllers can block clients with random MAC addresses using the **local-admin-mac deny** feature. This feature is disabled by default.

> **Note**
>
> This feature is not supported on Cisco Wave 1 access points.

Example: Denying Random MAC Address Clients

When the **local-admin-mac deny** knob is enabled on the controller, a client attempting to join the network with a random MAC address is rejected, preventing unauthorized or untraceable devices from accessing the wireless network.

For example, a phone may use a new random MAC address whenever it joins a public Wi-Fi network, which prevents tracking by Wi-Fi infrastructure or third parties.

Configure random MAC address denial (CLI)

Use this procedure to prevent clients with randomized MAC addresses from connecting to a wireless network by configuring random MAC address denial in the CLI.

Prevent unauthorized or random MAC devices from associating with your WLAN by enabling the random MAC address denial feature on your wireless controller through the CLI.

To stop the entry of clients with random MAC addresses from joining a wireless network, enable the random MAC address deny knob by following these steps.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the WLAN policy profile.

Example

```
Device(config)# wlan wlan-profile-name <1-4096> SSID-network-name
```

3. Shut down the WLAN.

Example

```
Device(config-wlan)# shutdown
```

4. Enable the random MAC address deny knob.

Example

```
Device(config-wlan)# local-admin-mac deny
```

Use the **no** form of this command to disable the feature.

5. Enable the WLAN.

Example

```
Device(config-wlan)# no shutdown
```

6. Save the configuration, exit the configuration mode, and return to privileged EXEC mode.

Example

```
Device(config-wlan)# end
```

Devices using randomized MAC addresses are prevented from joining the specified wireless SSID.

Verify denial of clients with a random MAC address

Verify Denial of Clients with a Random MAC Address.

To verify the denial of a client with a random MAC address, run the **show wlan name** *wlan-profile-name* **| begin locally** command:

```
Device# show wlan name laa | begin locally
Locally Administered Address Configuration
Deny LAA clients                          : Enabled
```

To verify if a client address is a random MAC address, run the **show wireless client mac-address** *MAC-address* **detail** command:

```
Device# show wireless client mac-address 72xx.38xx.2axx detail
Client MAC Address : 72xx.38xx.2axx
Client MAC Type    : Locally Administered Address
Client IPv4 Address      : 192.0.2.1
Client IPv6 Addresses    : 2001:DB8::71xx:27xx:a7xx:efxx
Client Username          : 72xx.38xx.2axx
```

To verify how many random MAC clients are present in the system, run the **show wireless stats client detail** command:

```
Device# show wireless stats client detail
Client Summary
------------------------------
Current Clients : 1
Excluded Clients: 0
Disabled Clients: 0
Foreign Clients : 0
Anchor Clients  : 0
Local Clients   : 1
Idle Clients    : 0
Locally Administered MAC Clients: 1
```

To display the statistics of a specific client, run the **show wlan id** *<1-4096>* **client stats** command:

```
Device# show wlan id 8 client stats
Wlan Profile Name: wlan-profile, Wlan Id: 8
Current client state statistics:
------------------------------------------------------------------------------

  Authenticating         : 0
  Mobility               : 0
  IP Learn               : 0
  WebAuth Pending        : 0
  Run                    : 1
Locally Administered MAC Clients         : 1
```

Note

Run the **show configuration wlan wlan-name** command on an AP, to view the status of the locally administered address (LAA) on the WLAN.

104 Dataplane Packet Logging

Topics:

- Dataplane packet logs

This chapter explains how to enable, configure, verify, and clear packet logging for wireless clients, including global and filtered trace buffers, CLI commands for ingress and punt-inject paths, and examples for troubleshooting DHCP, ARP, and CAPWAP issues.

Dataplane packet logs

This concept explains how dataplane packet logs capture and display packet information for onboarding and debugging wireless clients. It describes logging categories, features, and the types of network packets collected for troubleshooting.

A dataplane packet log is a diagnostic feature that

- captures connectivity and protocol packets (such as DHCP, Neighbor Discovery, and ARP) exchanged between wireless clients and the controller,
- helps you debug client onboarding and network communication issues, and
- offers unconditional (global) and selective (filtered) packet logging modes.

Expanded explanation

While onboarding wireless clients, you might encounter problems such as client IP address allocation, Address Resolution Protocol (ARP) resolution, and other connectivity issues. All of these issues require debugging.

For rapid troubleshooting, the controller logs Dynamic Host Configuration Protocol (DHCP), Neighbor Discovery, and ARP packets exchanged with wireless clients by default.

Packet logging categories

You can use packet-logging categories to capture connectivity information for wireless clients.

- **Global Trace Log**: Captures client connectivity information and is enabled by default.
- **Filtered Trace Log**: Lets you log packets to a filtered buffer. You enable filters using **debug** commands. Filters capture only specific packet types or packets associated with particular client MAC addresses.

Features of dataplane packet logs

- You can add or remove filters to customize the packet types captured. By default, DHCP, Neighbor Discovery, and ARP packets are always included.
- You can use display filters to select a subset of logged packets to review.
- You can use packet-logging data to view detailed debugging information such as client MAC address, client IP address, VLAN, interface, packet type, and time delta.

Dataplane packet log examples

- For onboarding issues, enable filtered trace logs with specific filters to capture only DHCP packets from a problematic client.
- Use display filters to narrow the logs to packets exchanged on a particular VLAN or interface.

Enable or disable debug level (CLI)

Use this procedure to enable or disable the debug level for wireless datapath trace-buffer using CLI commands.

Adjust the debug level for tracing wireless datapath operations on the device.

Procedure

1. Enable privileged EXEC mode.

Example

```
Device> enable
```

Enter your password, if prompted.

2. Enable the debug level to trace global and filtered logic.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer debug-level {all | error | info | trace | warning}
```

Example

```
Device# debug platform hardware chassis active qfp feature wireless datapath
 trace-buffer debug-level all
```

Use the **no** form of this command to disable the feature.

The specified debug level is enabled or disabled for the wireless datapath trace-buffer.

Enable packet logging in the global and filtered buffers in the ingress-path (CLI)

Use this task to enable packet logging in the global and filtered buffers in the ingress-path using CLI commands.

Enable detailed packet logging in the ingress-path of your device to troubleshoot and analyze network traffic.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

Enter your password if prompted.

2. Enable the quantum flow processor for the global-trace buffer in the ingress-path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer ingress global-trace
```

Use the **no** form of this command to disable the feature.

3. Enable Control and Provisioning of Wireless Access Points (CAPWAP) packet logging to the filtered-trace buffer in the ingress-path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer ingress filtered-trace capwap ipv4 209.165.200.224/27
```

Use the **no** form of this command to disable the feature.

4. Enable logging of wireless client packet information to the filtered-trace buffer in the ingress-path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer ingress filtered-trace wlclient {ipv6-nd | ipv6-ra |
mac-address H.H.H}
```

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer ingress filtered-trace wlclient ipv6-nd
```

Use the **no** form of this command to disable the feature.

The device captures and logs packet information for analysis in the global-trace and filtered-trace buffers of the ingress-path.

Enable packet logging in global and filtered buffers for the punt-inject path (CLI)

Learn how to enable packet logging in the global and filtered buffers for the punt-inject path using CLI commands.

Enable detailed packet logging to monitor traffic for troubleshooting on specific data paths.

Procedure

---

1. Enter privileged EXEC mode.

Example

```
Device> enable
```

Enter your password if prompted.

2. Enable the quantum flow processor in the global trace buffer for the punt-inject path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer punt-inject global-trace
```

Use the **no** form of this command to disable the feature.

3. Enable CAPWAP packet logging to the filtered trace buffer for the punt-inject path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer punt-inject filtered-trace capwap {ipv4 A.B.C.D | ipv6
 X:X:X:X::X | keepalive}
```

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer punt-inject filtered-trace capwap ipv4 209.165.200.224/27
```

Use the **no** form of this command to disable the feature.

4. Enable wireless client packet logging to the filtered trace buffer for the punt-inject path.

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer punt-inject filtered-trace wlclient {ipv6-nd | ipv6-ra
 | mac-address H.H.H}
```

Example

```
Device# [no] debug platform hardware chassis active qfp feature wireless
datapath trace-buffer punt-inject filtered-trace wlclient ipv6-nd
```

Use the **no** form of this command to disable the feature.

You have enabled packet logging for the global and filtered trace buffers in the punt-inject path.

Verify dataplane packet logging

Verify Dataplane Packet Logging.

To show trace buffer-configured conditions, use this command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer
 ingress conditions
LogTrace Event: Enabled
Trace wlclient-MACs:
    8c85.90ee.ca92
allow_all_AP_kalives: enabled
AP_kalive cnt=1, AP_kalive6 cnt=0
  IP0: 49.1.0.73
```

To view all the log entries in the filtered trace buffer, use this command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer
 ingress filtered-trace all
Trace wlclient-MACs: 8c85.90ee.ca92
  Trace-Buffer for Ingress: Enabled
  Total allocated global-log buffer: 16384
  Total allocated filtered-log v=buffers: 4096

<0 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213207 c=0
<1 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213236 c=0
<2 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213264 c=0
<3 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213293 c=0
<4 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
```

```
 dt=213321 c=0
<5 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213350 c=0
```

To view the number of entries based on a count, use this command:

```
Device# show platform hardware chassis active qfp feature wireless trace-buffer
 ingress filtered-trace 3
Trace wlclient-MACs: 8c85.90ee.ca92
  Trace-Buffer for Ingress: Enabled
  Total allocated global-log buffer: 16384
  Total allocated filtered-log v=buffers: 4096

<18 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213720 c=0
<19 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213748 c=0
<20 KEEP_ALIVE: CAPWAP peer=49.1.0.73 udp=5256 local=49.1.1.2 udp=5247 vlan=49,
 dt=213777 c=0

>> 3 entries displayed
   21 entries found in filtered-log buffer
   21 entries ever collected for filtered-log buffer
```

Clear logs and conditions in global and filtered trace buffers

Clear Logs and Conditions in Global and Filtered Trace Buffers.

To clear conditions and logs in the global and filtered trace buffers, use these commands:

```
Device# clear platform hardware chassis active qfp feature wireless trace-buffer
 ingress all
Trace, clear all trace configuration & buffer.

Device# clear platform hardware chassis active qfp feature wireless trace-buffer
 ingress conditions
Trace, clear trace configuration

Device# clear platform hardware chassis active qfp feature wireless trace-buffer
 ingress filtered-trace
Trace, clear trace Q

Device# clear platform hardware chassis active qfp feature wireless trace-buffer
 ingress global-trace
Trace, clear trace global Q
```

105 Streaming Telemetry

Topics:

- Streaming telemetry
- Client event and SSID telemetry filters

This chapter explains configuring and troubleshooting native streaming telemetry for Cisco wireless controllers and APs, including gather points, transports (gNMI/gRPC), subscription/session modes, scale limits, on-change support, zero-trust setup, and SSID/client filtering.

Streaming telemetry

This concept explains how telemetry streams provide a modern, structured approach for monitoring and troubleshooting network health by transmitting configuration and operational data from the controller to remote management stations.

A telemetry stream is a network monitoring method that:

- streams configuration and operational data from controllers in real time
- transmits data in a structured format to remote management stations
- enables efficient monitoring and troubleshooting of Wi-Fi and system health
- Telemetry feed: a specific subscription within a telemetry stream that delivers the selected data elements.
- Collector: the remote management station that receives telemetry data for analysis.

Streaming telemetry capabilities and usage

You can use streaming telemetry for scalable and efficient monitoring of access points and clients through native Cisco wireless models.

- You can enhance telemetry support to monitor up to 1,000 access points and 15,000 clients.
- Use a single collector setup to subscribe to the required XPaths.
- Use a telemetry feed to subscribe to data elements and monitor access points and clients.
- You receive data through the native Cisco wireless models.

Gather points

This concept explains how gather points serve as the top-level XPaths that define the smallest unit of data export in telemetry, enabling efficient and comprehensive data subscriptions.

A gather point is a data grouping mechanism that

- represents a top-level XPath in the telemetry data model
- acts as the smallest unit of data exported by a target device, and
- ensures subscriptions receive all data leaves defined beneath that point.

Supported gather points and subscription intervals

This table lists supported gather points and the minimum subscription intervals for each:

Table 102: Supported gather points and subscription intervals

Supported gather point	Subscription interval
wireless-access-point-oper:access-point-oper-data/ethernet-mac-wtp-mac-map	>=15 mins
/wireless-access-point-oper:access-point-oper-data/capwap-data	>=15 mins
/wireless-access-point-oper:access-point-oper-data/cdp-cache-data/	>=15 mins
/wireless-access-point-oper:access-point-oper-data/radio-oper-stats	>=60 secs
/wireless-access-point-oper:access-point-oper-data/radio-oper-data	>=180 secs

Supported gather point	Subscription interval
/wireless-access-point-oper:access-point-oper-data/oper-data	>=180 secs
/wireless-rrm-oper:rrm-oper-data/rrm-measurement	>=180 secs
/wireless-client-oper:client-oper-data/dot11-oper-data	>=180 secs
/wireless-client-oper:client-oper-data/common-oper-data	>=15 mins
/wireless-client-oper:client-oper-data/policy-data	>=60 secs
/wireless-client-oper:client-oper-data/sisf-db-mac/ipv4-binding/ip-key/ip-addr	>=15 mins
/wireless-client-oper:client-oper-data/traffic-stats	>=180 secs
/lldp-ios-xe-oper:lldp-entries/lldp-state-details	>=60 secs
/device-hardware-xe-oper:device-hardware-data/device-hardware	>=15 mins
/wireless-mobility-oper:mobility-oper-data/mobility-node-data/ulink-status	>=60 secs
/process-cpu-ios-xe-oper:cpu-usage/cpu-utilization/one-minute	>=60 secs
/platform-sw-ios-xe-oper:cisco-platform-software/control-processes	>=60 secs
/environment-ios-xe-oper:environment-sensors/environment-sensor	>=60 secs
/lldp-ios-xe-oper:lldp-entries/lldp-intf-details	>=60 secs
/interfaces-ios-xe-oper:interfaces/interface	>=60 secs
/platform-ios-xe-oper:components/component	>=60 secs
/mdt-oper-v2:mdt-oper-v2-data	>=60 secs
/wireless-access-point-oper:access-point-oper-data/radio-oper-data/radio-band-info	>=180 secs

Example of gather point subscription

When you subscribe to an XPath such as */access-point-operdata/radio-oper-data/vap-oper-config/ssid*, which is part of the gather point */access-point-operdata/radio-oper-data/vap-oper-config*, the reply will include all attributes that are part of the gather point, such as AP-VAP-ID, SSID, and WLAN ID.

Subscription

This concept explains how subscriptions connect one or more gather points with destinations, enabling cadence-based data streaming using Multicast Default Transport (MDT).

A subscription is a configuration that

- binds one or more gather points and destinations
- streams data for each gather point using MDT, and
- operates at a configured cadence (frequency).

Transport

This concept explains the transport protocols available for publisher-to-receiver connections and how they determine the method and encoding of data transmission in the system.

A transport is a protocol that:

- enables a connection between a publisher and a receiver
- determines how data is transmitted
- operates independently from the management protocol used for configured subscriptions
- The choice of transport protocol affects compatibility and the data formats exchanged between systems.
- The supported transport protocols are gNMI (gRPC Network Management Interface) and gRPC (Google Remote Procedure Call).
- The gNMI transport protocol supports JSON encoding of data.
- The gRPC transport protocol supports key value Google Protocol Buffers (kvGPB: key value Google Protocol Buffers) encoding.

Scale considerations

This topic explains the scale numbers that are applicable to the native model for an XPath set.

This table provides the scale numbers that are applicable to the native model for an XPath set.

Table 103: Scaling considerations to the native model

Attribute	Scale
AP	4000
Client	15000
SSID per AP	6
BSSID per AP	12
Neighbors per AP	60 (30x2)
Number of physical neighbor APs	49
Number of neighbor records	60000 records

Session

This concept explains what sessions are in network telemetry and describes their core attributes and available initiation modes.

A session is a telemetry connection that

- enables data exchange between the controller and the receiver
- may be initiated by the user, and
- supports two modes: gNMI Dial-In and gRPC Dial-Out.

Session initiation modes

You can initiate a session between the controller and the receiver using these modes:

- gNMI Dial-In Mode
- gRPC Dial-Out Mode

gNMI dial-in modes

This concept explains how gNMI dial-in modes enable a telemetry receiver to initiate and manage dynamic subscriptions to a controller for real-time telemetry data streaming.

A gNMI dial-in mode is a telemetry subscription mechanism that:

- enables a Model-Driven Telemetry (MDT) receiver to connect directly to the controller
- allows the receiver to dynamically subscribe to one or more gather points or subscriptions, and
- streams telemetry data from the controller to the receiver over the established session until the subscription is canceled or the session is terminated

Reference Information for gNMI Dial-In Mode

In gNMI dial-in mode, the MDT receiver (client) initiates a connection ("dials in") to the controller (server). After connecting, the receiver can select and change the telemetry data it wants to receive by subscribing to specific gather points (subscriptions).

The controller streams the selected telemetry data to the receiver over the same session. Subscriptions in dial-in mode are temporary. They end when the receiver cancels the subscription or disconnects. This differs from persistent, controller-initiated subscriptions.

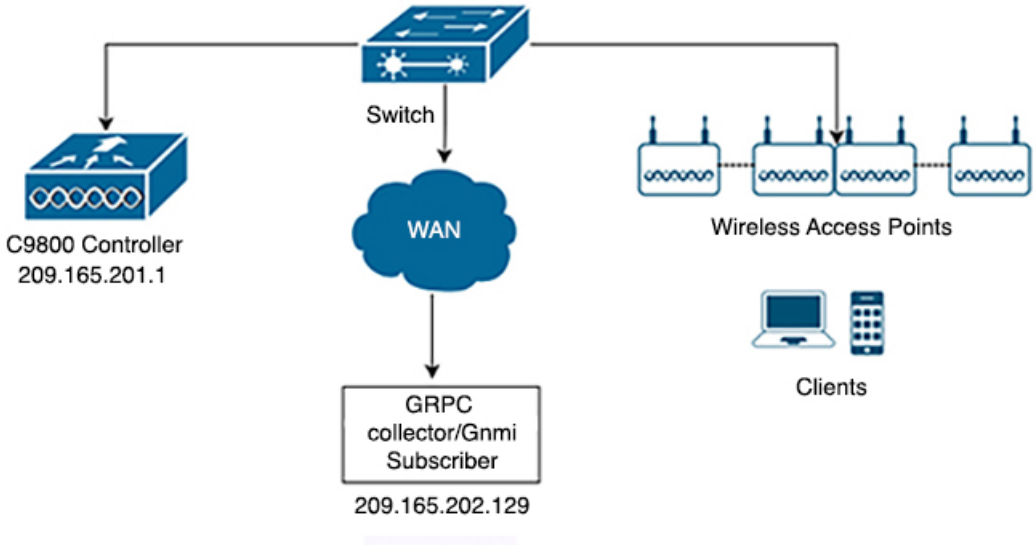
Example of gNMI Dial-In Mode

A network operations system uses gNMI dial-in mode to gather real-time interface statistics from a controller. The system connects as a client, subscribes to the desired telemetry data, and continues receiving updates until it cancels the subscription and terminates the session.

gRPC dial-out modes

This concept explains gRPC dial-out modes. It describes how the controller acts as a client to stream telemetry data to receivers by using persistent subscriptions.

A gRPC dial-out mode is a telemetry delivery method that:



- enables the controller to act as a client and initiate outbound connections to receivers
- binds gather points and destinations into subscriptions that continually deliver telemetry data
- streams data to receivers and continually maintains sessions for each configured destination

Additional reference information

In dial-out mode, the controller contacts the receiver, which acts as a server. Configure gather points and destinations and link them into one or more subscriptions.

The controller establishes and maintains sessions with each destination in the subscription to ensure continuous data streams. Subscriptions in this mode remain persistent.

Figure 10: Telemetry Session

Note

If you remove a VRF (Virtual Routing and Forwarding) definition and link it to a telemetry source interface, configure these commands with the name server settings to ensure DNS resolution works correctly:

```
ip domain lookup vrf <vrf name> source-interface <>
```

```
ip name-server vrf <vrf name> <domain server ip>
```

Configure telemetry on controllers

This process shows you how to configure telemetry on a controller. You enable the gRPC Network Management Interface (gNXI) in secure and insecure modes. You also verify subscriptions and manage configured subscriptions.

Summary

You enable gNXI in different modes. You verify the status of telemetry subscriptions. You manage existing subscriptions on the controller.

Workflow

You can configure telemetry on a controller by completing these steps.

1. Enable gNXI in insecure mode.
2. Enable gNXI in secure mode.
3. Verify the status of the subscription.
4. Manage configured subscriptions.

Result

The controller is configured for telemetry. You can validate and manage the desired subscriptions.

This configuration supports real-time monitoring and reporting.

Enable the gRPC Network Operations Interface (gNXI) in Insecure Mode (CLI)

Enable the gNXI server in insecure mode using CLI commands.

Enable the gNXI server in insecure mode. Use this mode for testing or non-production environments that do not require certificate-based security.

The gRPC Network Operations Interface (gNXI) is a network management protocol. In insecure mode, the server does not use certificate-based authentication or encrypted communication.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Start the gNXI process.

   Example

   ```
   Device(config)# gnxi
   ```

4. Enable the gNXI server in insecure mode.

   Example

   ```
   Device(config)# gnxi server
   ```

5. Set the gNXI port.

   Example

   ```
   Device(config)# gnxi port-number
   ```

   The default insecure gNXI port is 9339.

6. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

7. View the status of the gNXI server.

Example

```
Device# show gnxi state
```

The gNXI server operates in insecure mode. It listens for incoming connections on the specified port.

Verify the status using the **show gnxi state** command.

This example shows sample output from the **show gnxi state** command:

```
Device# show gnxi state
State Status
--------------------------------
Enabled Up
```

Enable gNXI in Secure Mode (CLI)

Enable gNXI in secure mode using CLI commands. This configuration provides secure communication and authentication between your device and gNXI clients.

Enable gNXI in secure mode so your device securely interfaces with gNXI clients. This setup uses certificate-based authentication and encrypted communication.

gRPC Network Operations Interface (gNXI) is a modern protocol for network management. Secure mode encrypts and authenticates all gNXI communication.

Use this task if you deploy devices in environments where security is critical or compliance mandates certificate-based authentication for management protocols.

Procedure

---

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password if prompted.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Start the gNXI process.

   Example

   ```
   Device(config)# gnxi
   ```

4. Enable the gNXI server in secure mode.

Example

```
Device(config)# gnxi secure-server
```

5. Specify the trustpoint and certificate set that gNXI uses to authenticate clients.

   Example

   ```
   Device(config)# gnxi secure-trustpoint trustpoint-name
   ```

6. Optional: Enable client certificate authentication.

   Example

   ```
   Device(config)# gnxi secure-client-auth
   ```

   gNXI authenticates client certificates against the root certificate you configure.

7. Optional: Set the gNXI port number.

   Example

   ```
   Device(config)# gnxi secure-port
   ```

   If you do not enable secure mode, gNXI uses port 9,339 by default.

8. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

9. Display the gNXI server's status to confirm your configuration.

   Example

   ```
   Device# show gnxi state
   ```

The device enables gNXI in secure mode using the configured trustpoint and port. The device allows secure, certificate-authenticated connections from gNXI clients.

This is sample output from the **show gnxi state** command:

```
Device# show gnxi state
State Status
--------------------------------
Enabled Up
```

Verify the status of a telemetry subscription on a controller

This topic explains how to verify the status of a telemetry subscription on a Cisco Catalyst 9800 Series Wireless Controller using various show commands.

To verify the status of a subscription, use these commands:

```
Device# show telemetry ietf subscription all
Device# show telemetry ietf subscription 101
Device# show telemetry ietf subscription 101 detail
Device# show telemetry ietf subscription 101 receiver
Device# show telemetry internal connection
Device# show telemetry internal subscription all stats
Device# show telemetry receiver all
Device# show telemetry receiver name <receivers-name>
Device# show telemetry connection all
```

Manage configured subscriptions on a controller (CLI)

Learn how to manage configured subscriptions on a Cisco Catalyst 9800 Series Wireless Controller using the CLI.

Configure telemetry subscriptions to collect data from supported YANG models and stream data to remote receivers on a controller.

Use the **show platform software ndbman switch** { *switch-number* | **active** | **standby** } **models** command to display the list of YANG models that support on-change subscription.

> **Note**
>
> Currently, you can only use the gRPC protocol for managing configured subscriptions.

Procedure

1. Enable privileged EXEC mode.

   Example

   ```
   Device# enable
   ```

   Enter your password, if prompted.

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Create a telemetry subscription and enter telemetry-subscription mode.

   Example

   ```
   Device(config)#  telemetry ietf subscription id
   ```

4. Specify the Key-value Google Protocol Buffers (kvGPB) encoding.

Example

```
Device(config-mdt-subs)# encoding encode-kvgpb
```

5. Specify the XPath filter for the subscription.

Example

```
Device(config-mdt-subs)# filter xpath path
```

6. Configure the source IP address on the telemetry subscription interface.

Example

```
Device(config-mdt-subs)# source-address { A.B.C.D | X:X:X:X::X }
```

7. Configure a stream for the subscription.

Example

```
Device(config-mdt-subs)# stream yang-push path
```

8. Configure a periodic update policy for the subscription.

Example

```
Device(config-mdt-subs)# update-policy periodic period
```

9. Configure a periodic update policy for the subscription.

Example

```
Device(config-mdt-subs)# receiver ip address ip-address receiver-port  protocol
  protocol profile name
```

Example

```
Device(config-mdt-subs)# receiver ip address 209.165.201.1 protocol grpc-tcp
```

10. Exit telemetry-subscription configuration mode and return to privileged EXEC mode.

Example

```
Device(config-mdt-subs)# end
```

The telemetry subscription is configured, and the controller pushes YANG model data to the defined receiver using the gRPC protocol.

Configure zero trust telemetry

This process describes how to configure zero trust telemetry on a Cisco Catalyst 9800 Series Wireless Controller, including defining a protocol, naming a receiver, and setting up a telemetry subscription.

Summary

Zero trust telemetry provides enhanced monitoring and security by collecting and transmitting telemetry data from the controller.

Workflow

The stages describe the steps to configure zero trust telemetry on the controller.

1. Define a protocol for telemetry communication on the controller.
2. Define a named receiver to receive telemetry data.
3. Configure the telemetry subscription to enable data collection and transmission.

Define a protocol (CLI)

Use this procedure to configure a telemetry protocol profile for secure telemetry communication using gRPC.

Securely configure telemetry data export protocols by defining protocol profiles with appropriate trustpoints.

Before you begin

Define crypto trustpoints (CAforMDTserver and IDforWLCclient) and certificates before the telemetry configuration.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the protocol gRPC profile and enter gRPC profile name.

   Example

   ```
   Device(config)# telemetry protocol grpc profile profile-name
   ```

3. Add the server CA trustpoint.

   Example

   ```
   Device(config-mdt-protocol-grpc-profile)# ca-trustpoint CAforMDTserver
   ```

4. Add the client ID trustpoint.

   Example

   ```
   Device(config-mdt-protocol-grpc-profile)# id-trustpoint wlc-id-trustpoint
   ```

The telemetry protocol profile is configured with the specified trustpoints.

Define a named receiver (CLI)

Use this procedure to define a named receiver for telemetry configuration.

Define a named receiver and associate an FQDN and TLS profile for telemetry data delivery.

This procedure defines:

- FQDN DNS name
- Crypto protocol definition

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the receiver name.

   Example

   ```
   Device(config)# telemetry receiver protocol receiver-name
   ```

3. Add FQDN DNS name of receiver.

   Example

   ```
   Device(config-mdt-protocol-receiver)# host name FQDN-receiver
   ```

4. Define the gRPC TLS profile named mtlsyang.

   Example

   ```
   Device(config-mdt-protocol-receiver)# protocol grpc-tls profile profile-name
   ```

The device is now configured with a named telemetry receiver with the specified parameters.

Configure a telemetry subscription (CLI)

Use this procedure to configure a telemetry subscription on the device using the CLI. This enables streaming of selected network data for monitoring by external collectors.

Set up telemetry subscriptions to send device data to external receivers for analysis and monitoring.

This procedure configures:

- Xpath
- Named receiver
- Protocol

Procedure

1. Enable privileged EXEC mode. Enter your password, if prompted.

Example

```
Device# enable
```

2. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

3. Create a telemetry subscription and enter telemetry-subscription mode.

   Example

   ```
   Device(config)# telemetry ietf subscription id
   ```

4. Specify the key-value Google Protocol Buffers (kvGPB) encoding.

   Example

   ```
   Device(config-mdt-subs)# encoding encode-kvgpb
   ```

5. Specify the XPath filter for the subscription.

   Example

   ```
   Device(config-mdt-subs)# filter xpath path
   ```

6. Configure the source IP address on the telemetry subscription interface.

   Example

   ```
   Device(config-mdt-subs)# source-address ip-address  A.B.C.D | X:X:X:X::X
   ```

7. Configure a stream for the subscription.

   Example

   ```
   Device(config-mdt-subs)# stream yang-push
   ```

8. Configure a periodic update policy for the subscription.

   Example

   ```
   Device(config-mdt-subs)# update-policy periodic period
   ```

9. Configure type protocol for receiver.

   Example

   ```
   Device(config-mdt-subs)# receiver-type protocol
   ```

10. Specify the receiver name.

Example

```
Device(config-mdt-subs)# receiver name collector
```

11. Exit telemetry-subscription configuration mode and return to privileged EXEC mode.

Example

```
Device(config-mdt-subs)# end
```

The device is configured to stream selected data to the named receiver using the specified encoding and update policy.

On-Change Telemetry Support

On-Change Telemetry Support details.

From Cisco IOS XE Cupertino 17.7.1 onwards, on-change telemetry support is provided to a subset of XPaths.

Supported XPaths for on-change subscription

This topic explains the supported XPaths for on-change subscription, including those introduced in various Cisco IOS XE YANG models and their corresponding gather points, EXEC CLIs, and telemetry feeds.

The tables list the supported XPaths for on-change subscription. Each section provides the relevant gather points, EXEC CLIs, or telemetry feeds associated with Cisco IOS XE YANG models.

Supported gather points and XPaths

This table lists the supported XPaths for on-change subscription.

Gather points	XPaths
/access-point-oper-data/radio-operdata/	/access-point-oper-data/radio-operdata/phy-ht-cfg/cfg-data/curr-freq /access-point-oper-data/radio-operdata/phy-ht-cfg/cfg-data/chan-width /access-point-oper-data/radio-oper-data/current-band-id

Gather points	XPaths
/access-point-oper-data/capwap-data	/access-point-oper-data/capwap-data/name
	/access-point-oper-data/capwapdata/device-detail/wtp-version/sw-ver/version
	/access-point-oper-data/capwap-data/device-detail/wtp-version/sw-ver/release
	/access-point-oper-data/capwapdata/device-detail/wtp-version/sw-ver/maint
	/access-point-oper-data/capwapdata/device-detail/wtp-version/sw-ver/build
	/access-point-oper-data/capwap-data/ap-state/ap-operation-state
	/access-point-oper-data/capwapdata/device-detail/static-info/board-data/wtp-serial-num
/access-point-oper-data/oper-data	/access-point-oper-data/oper-data/ap-ip-data/ap-ip-addr
	/access-point-oper-dat/oper-data/ap-pow/power-type

Supported gather points and XPaths (Cisco-IOS-XE-wireless-ap-global-oper-transform.yang)

Gather oints	XPaths
/ap-global-oper-data/ap-join-stats/wtp-mac	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-ethernet-mac
	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-name
	/ap-global-oper-data/ap-join-stats/ap-join-info/ap-ip-addr
	/ap-global-oper-data/ap-join-stats/ap-join-info/is-joined
	/ap-global-oper-data/ap-join-stats/ap-join-info/last-error-type
	/ap-global-oper-data/ap-join-stats/ap-disconnect-reason

Supported gather points and XPaths (Cisco-IOS-XE-aaa-oper.yang)

Gather Points	Xpaths
/aaa-data/aaa-radius-stats/	/aaa-data/aaa-radius-stats/radsec-pkt-cnt-idletime
	/aaa-data/aaa-radius-stats/radsec-send-hs-start-cnt
	/aaa-data/aaa-radius-stats/radsec-hs-success-cnt

Troubleshooting Telemetry Support

This section lists recommended commands, checks, and analysis steps for collecting telemetry diagnostics from Cisco Catalyst 9800 Series Wireless Controllers, with an emphasis on gRPC telemetry troubleshooting and supporting TAC case resolution.

This document outlines a set of commands and procedures to help you systematically gather data and diagnose telemetry-related issues.

Key factors to consider before troubleshooting

- Provide a clear problem description.
- Identify any recent changes in the network.
- Determine the previous known good state.
- Assess the overall impact of the problem.

Timestamp logging recommendation

Run all the **show** commands with **show clock** or **terminal exec prompt timestamp** once to log timestamps automatically.

General commands for all telemetry cases

For every issue, run these commands:

1. `Device# terminal length 0`
2. `Device# show clock`
3. `Device# show tech-support wireless`
4. `Device# request platform software trace archive last 1`

Basic checks for telemetry function

1. Verify that the requisite processes (particularly pubd) are running using this commands:

```
show platform software yang-management process
```

2. Capture and validate the telemetry-specific configuration using this command:

```
show running-config | section telemetry
```

3. Check the validity of any subscriptions using this command:

```
show telemetry ietf subscription all
```

4. Check the validity of any named receivers using this command:

```
show telemetry receiver all
```

5. Verify the telemetry subscription states using this command:

```
show telemetry internal subscription all stats
```

Checking telemetry connectivity

1. Check the state of the subscription receiver using this command:

```
show telemetry ietf subscription <id> receiver
```

2. Check the state of telemetry connections using the following command:

```
show telemetry connection all
```

3. Check which subscriptions use a particular connection using the following command:

```
show telemetry connection <index> subscription
```

Capture debug logs for telemetry

1. Enable these debug options:

```
set platform software trace mdt-pubd chassis active r0 mdt-ctrl debug
set platform software trace mdt-pubd chassis active r0 pubd debug
set platform software trace mdt-pubd chassis active r0 green-be debug
set platform software trace mdt-pubd chassis active r0 green-fe debug
```

```
set platform software trace mdt-pubd chassis active r0 dbal debug
set platform software trace mdt-pubd chassis active r0 tdllib debug
set platform software trace ios chassis active r0 green-be debug
set platform software trace ios chassis active r0 dbal debug
set platform software trace ios chassis active r0 tdllib debug
```

2. Recreate the problem.
3. Collect debug logs:

```
request platform software trace archive last <days>
```

4. Disable debugging using these commands:

```
set platform software trace mdt-pubd chassis active r0 mdt-ctrl notice
set platform software trace mdt-pubd chassis active r0 pubd notice
set platform software trace mdt-pubd chassis active r0 green-be notice
set platform software trace mdt-pubd chassis active r0 green-fe notice
set platform software trace mdt-pubd chassis active r0 dbal notice
set platform software trace mdt-pubd chassis active r0 tdllib notice
set platform software trace ios chassis active r0 green-be notice
set platform software trace ios chassis active r0 dbal notice
set platform software trace ios chassis active r0 tdllib notice
```

General telemetry diagnostics

To capture general telemetry diagnostics, use this command:

```
show telemetry internal diagnostics
```

Generate a process core

Generate a core using these commands:

1. `show clock`
2. `configure terminal`
3. `service internal`
4. `end`
5. `request platform software process core mdt-pubd chassis active r0`

Disable logging

Disable the logging using these commands:

1. `configure terminal`
2. `no service internal`
3. `end`

Capture CPU and memory data for telemetry processes

To capture CPU memory details use the following commands:

- `show processes cpu platform sorted | i pubd`
- `show processes memory platform sorted | s pubd`

Client event and SSID telemetry filters

This concept explains client event and SSID telemetry filters, which enable selective filtering of telemetry data for specific SSIDs to address scaling challenges in environments with many transient guest clients.

A client event and SSID telemetry filter is a feature that

- filters telemetry data for specific SSIDs to separate transient guest client data from clients requiring assurance,
- reduces scaling challenges by minimizing high-frequency telemetry data from transient clients, and
- enables configuration and management through controller and access point profiles.

Feature History for client event and SSID telemetry filters

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 104: Feature History

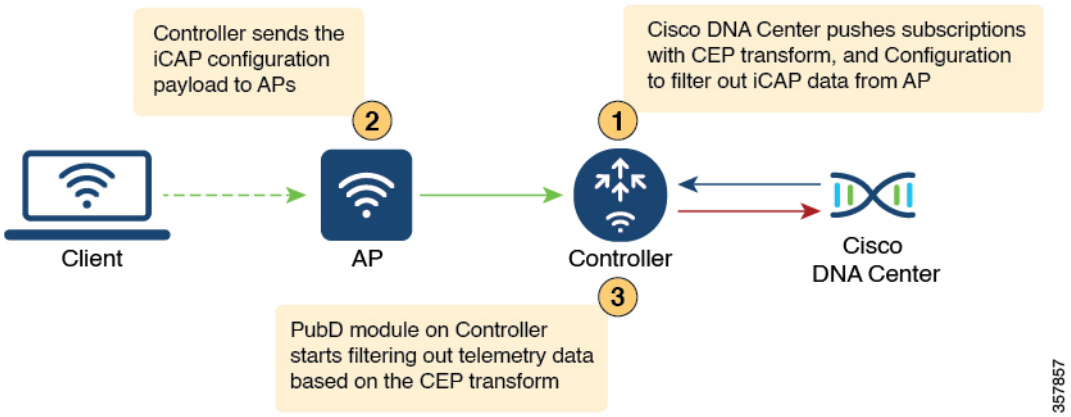
Release	Feature	Feature information
Cisco IOS XE Dublin 17.10.1	Cisco Catalyst Center Client Event and SSID Telemetry Filter	This feature filters out telemetry data for a configured SSID on the controller and AP.

Example: Filtering telemetry data for a guest SSID

For instance, in a large airport, the administrator configures the filter for the "Guest-WiFi" SSID. The controllers and APs then exclude telemetry data from transient guest clients, ensuring that only relevant data from corporate clients is processed and stored.

How the Client Event and SSID Telemetry Filter Works

This process explains how the client event and SSID telemetry filter operates in large enterprise environments. It outlines the key components, the filtering stages, and how the filter reduces unnecessary telemetry data processing and storage.



In environments such as airports and shopping malls, large numbers of transient guest clients can overwhelm telemetry systems. The filter allows administrators to configure which SSIDs' telemetry data is excluded from processing and storage.

- Telemetry data for configured SSIDs is filtered at both the controller and access point (AP) levels.
- The Complex Event Processing (CEP) transform is configured with the SSID to be filtered, and the Publishing Daemon (PubD) module in the controller enforces the filter.
- Filtered data types include client events, client statistics, AP or RF statistics, partial PCAP, and anomaly detection.

To debug filtering at PubD, run the following commands on the controller:

- `set platform software trace mdt-pubd chassis active r0 pubd debug`
- `set platform software trace mdt-pubd chassis active r0 mdt-xfrm debug`

Figure 11: High-Level End-to-End System Flow for Cisco Catalyst Center Client Event and SSID Telemetry Filter

Note

The Cisco Catalyst Center automation pushes the transforms. Enable or disable filtering for a specific SSID in the controller GUI.

Summary

This process enables administrators to selectively filter telemetry data for specified SSIDs in large-scale wireless environments. Configuring filters at both the controller and access point levels prevents unnecessary client and SSID telemetry data from being processed or stored. This improves system performance and scalability.

Workflow

1. Configure the CEP transform with the SSID to be filtered in Cisco Catalyst Center.
2. The controller applies the filter and pushes the configuration to the APs.
3. The AP programs the **aptrace** module to drop packets and events for the filtered SSID.

Result

Telemetry data for configured SSIDs is excluded from processing and storage at both the controller and AP levels. This helps maintain system performance and prevents overload, especially in large environments with many transient clients.

Restrictions for Cisco Catalyst Center client event and SSID telemetry filter

Use these guidelines when configuring Cisco Catalyst Center Client Event and SSID Telemetry Filter to ensure proper application and avoid unsupported configurations.

- CLI configuration is applicable for WLAN and not SSID. The Cisco Catalyst Center automation covers one-to-one mapping of WLAN to SSID.
- Controller does not send any notification to Cisco Catalyst Center at the beginning or at the end of filtering.
- Controller GUI configuration is not supported.

Configure Client Event and SSID Telemetry Filters

This process explains how to configure client event and SSID telemetry filters in Cisco DNA Center by creating WLANs, mapping them to policy profiles, and associating filters through the AP Join Profile.

Summary

Configuring client event and SSID telemetry filters in Cisco DNA Center consists of several stages. These stages enable targeted monitoring and reporting for wireless networks.

Workflow

Follow these stages to configure client event and SSID telemetry filters:

1. Create WLANs for client devices.
2. Map each WLAN to a policy profile to define network and security policies.
3. Create and assign a filter for the WLAN in the AP Join Profile to collect event and telemetry data.

Result

After completing these stages, client event and SSID telemetry filters are applied. You can then monitor and report on wireless network activity in Cisco DNA Center.

Enable iCAP filter on AP (CLI)

Learn how to enable iCAP filtering on APs using CLI commands.

Enable iCAP filtering in AP profiles to manage data telemetry and enhance security for WLAN deployments.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

   Example

   ```
   Device(config)# ap profile ap-profile
   ```

3. Add a description for the AP profile.

Example

```
Device(config-ap-profile)# description ap-profile-name
```

4. Enable iCAP filtering in APs.

Example

```
Device(config-ap-profile)# icap subscription client exclude telemetry-data
wlan wlan-profile-name
```

---

iCAP filtering is enabled for the specified AP profile; the designated telemetry data will be excluded according to your configuration.

Disable client telemetry data for a WLAN (YANG)

Disable Client Telemetry Data for a WLAN (YANG).

To disable the client telemetry data for a WLAN, use this RPC model:

```
<nc:rpc xmlns:nc="urn:ietf:params:xml:ns:netconf:base:1.0"
message-id="urn:uuid:0a77124f-c563-469d-bd21-cc625a9691cc">
<nc:edit-config>
<nc:target>
<nc:running/>
</nc:target>
<nc:config>
<site-cfg-data xmlns="http://cisco.com/ns/yang/Cisco-IOS-XE-wireless-site-cfg">
<ap-cfg-profiles>
<ap-cfg-profile>
<profile-name nc:operation="merge">default-ap-profile</profile-name>
<icap-client-exclude-cfgs>
<icap-cient-exclude-cfg nc:operation="merge">
<wlan-profile nc:operation="merge">tel</wlan-profile>
</icap-client-exclude-cfg>
</cap-client-exclude-cfgs>
</ap-cfg-profile>
</ap-cfg-profiles>
</site-cfg-data>
</nc:config>
</nc:edit-config>
</nc:rpc>
```

For more information on YANG models, see the *Cisco IOS XE Programmability Configuration Guide* and YANG Data Models on Github at https://github.com/YangModels/yang/tree/master/vendor/cisco/xe.

You can contact the Developer Support Community for NETCONF/YANG features using this link:

https://developer.cisco.com/

Verify client telemetry data for WLAN

Verify client telemetry data for a WLAN.

To verify the client telemetry data for a WLAN, use this command:

```
Device# show running-config | section profile
ap profile default-ap-profile
 capwap retransmit count 8
 capwap timers primary-discovery-timeout 3000
 country IN
 description "default ap profile"
 icap subscription client exclude telemetry-data wlan guest
```

106 Application Performance Monitoring

Topics:

- APM
- Configure APM

APM

Introduces the core concepts of application performance monitoring and details specific restrictions that apply to its implementation in Cisco wireless deployments.

Application performance monitoring features are assurance solutions that

- collect and export assurance-related metrics for each application when flows are sent through specific AP interfaces
- aggregate these metrics using Cisco Catalyst 9800 Series controllers, and
- export the aggregated data to Cisco Catalyst Center for analysis.

Supported platforms

- Cisco Catalyst 9800 Series Controllers: 9800-80, 9800-40, 9800-L, and 9800-CL
- Cisco Catalyst 9100 Series APs in FlexConnect and fabric mode
- Cisco Catalyst 9300 Series and 9400 Series switches in fabric mode

> **Note**
>
> FNFv9 flows transit through the C9800 controller before being sent to Cisco Catalyst Center.

Supported monitors

- A general assurance monitor collects quantitative metrics for TCP and UDP flows, and qualitative metrics for TCP flows.
- A media monitor computes both qualitative and quantitative metrics for real-time protocol (RTP) flows.

Voice applications, such as Microsoft Teams and SIP, use RTP monitors. Other applications use TCP and UDP monitors.

A flow monitor can be attached to

- an interface that monitors all the flows from the attachment point.
- a wireless profile policy (the wireless profile policy that is associated with a WLAN or SSID) that monitors all the traffic passing through it.

Restrictions

Application Performance Monitoring restrictions.

- In FlexConnect and fabric mode, enable Application Performance Monitoring (APM) on a maximum of four WLANs. If APM is enabled on more than four WLANs, AP CAPWAP flaps might occur when APM is enabled or disabled, or when the AP mode is changed.
- Local flow exporter is not supported.
- These commands are not supported:
  - **show avc wlan application top**
  - **show avc client top application**

- You cannot configure Application Performance Monitoring and Application Visibility and Control basic on a single policy profile. You can configure each feature on separate policy profiles.
- During Control and Provisioning of Wireless Access Points (CAPWAP) restart, the AP moves to standby mode, and the nitro engine is disabled. When CAPWAP is up and the nitro engine is enabled, an attempt is made to classify the flows. Since there is not enough information to classify the applications, they are marked as unknown. When the AP rejoins CAPWAP, client traffic gets marked or classified correctly.
- When a client roams while an application has an active session, the specific session traffic is marked as unknown. The client has to start a new session to mark or classify the traffic correctly.

Configure APM

Guides the configuration of application performance monitoring by demonstrating how to create flow monitors, wireless WLAN policy profiles, policy tags, and attach policy profiles to APs, with steps for verifying the APM setup.

Create a flow monitor

Create a Flow Monitor using commands.

Configure flow monitors to collect wireless AVC assurance metrics.

Use these steps to set up flow monitors on a Cisco device for wireless assurance monitoring.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Create a flow monitor.

   Example

   ```
   Device(config)# flow monitor avc_assurance
   ```

3. Add a description to the flow monitor using the **description***description* command.

   Example

   ```
   Device(config-flow-monitor)# description assurance monitor ID is 90
   ```

4. Specify the IPv4 assurance metrics for wireless.

   Example

   ```
   Device(config-flow-monitor)# record wireless avc ipv4 assurance
   ```

5. Return to global configuration mode.

Example

```
Device(config-flow-monitor)# exit
```

6. Create a flow monitor.

Example

```
Device(config)# flow monitor avc_assurance_rtp
```

7. Add a description to the flow monitor using the **description***description* command.

Example

```
Device(config-flow-monitor)# description assurance-rtp monitor ID is 94
```

8. Specify the IPv4 assurance RTP metrics for wireless.

Example

```
Device(config-flow-monitor)# record wireless avc ipv4 assurance-rtp
```

9. Return to privileged EXEC mode.

Example

```
Device(config-flow-monitor)# end
```

The flow monitors for wireless AVC assurance and assurance RTP metrics are successfully created on the device.

Create a wireless WLAN profile policy

Create a wireless WLAN profile policy using commands.

Define and configure a WLAN policy profile using CLI commands for wireless network management.

Create a WLAN policy profile when you need to control traffic handling, enable advanced monitoring, or specify flow monitors for your wireless network on Cisco devices.

- Ingress flow monitors track incoming (received) traffic and help pinpoint what enters your wireless network.
- Egress flow monitors monitor outgoing (sent) traffic. This allows you to know what leaves your network.
- Multiple monitors (such as `avc_assurance` and `avc_assurance_rtp`) can be assigned to analyze different kinds of traffic or applications (for example, general application traffic and real-time media).

Before you begin

Know the profile name and flow monitor names you plan to use.

Procedure

---

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure the WLAN policy profile and enter wireless policy configuration mode.

   Example

   ```
   Device(config)# wireless profile policy policy-name
   ```

3. Disable the policy profile.

   Example

   ```
   Device(config-wireless-policy)# shutdown
   ```

4. Disable central switching.

   Example

   ```
   Device(config-wireless-policy)# no central switching
   ```

5. Specify the name of the IPv4 ingress flow monitor for general application traffic using the **ipv4 flow monitor** *monitor-name***input** command.

   Example

   ```
   Device(config-wireless-policy)# ipv4 flow monitor avc_assurance input
   ```

6. Specify the name of the IPv4 ingress flow monitor for real-time media traffic (RTP).

   Example

   ```
   Device(config-wireless-policy)# ipv4 flow monitor avc_assurance_rtp input
   ```

7. Specify the name of the IPv4 egress flow monitor for general application traffic.

   Example

   ```
   Device(config-wireless-policy)# ipv4 flow monitor avc_assurance output
   ```

8. Specify the name of the IPv4 egress flow monitor for real-time media traffic (RTP).

   Example

   ```
   Device(config-wireless-policy)# ipv4 flow monitor avc_assurance_rtp output
   ```

9. Enable the policy profile.

   Example

   ```
   Device(config-wireless-policy)# no shutdown
   ```

10. Return to privileged EXEC mode.

Example

```
Device(config-wireless-policy)# end
```

The WLAN policy profile is created and configured with the specified settings. Traffic monitoring and switching behavior are now defined by the profile.

Create a policy tag

Create a Policy Tag using commands.

Define and attach a policy tag to a WLAN using the CLI.

Policy tags associate WLANs with specific policies on a Cisco wireless controller. When you create a policy tag and link it to a WLAN, you can apply policy profiles.

Procedure

1. Enter global configuration mode.

Example

```
Device# configure terminal
```

2. Configure a policy tag and enter policy tag configuration mode.

Example

```
Device(config-policy-tag)# wireless tag policy policy-tag-name
```

3. Attach the policy tag to a WLAN.

Example

```
Device(config-policy-tag)# wlan wlan-avc  policy policy
```

4. Return to privileged EXEC mode.

Example

```
Device(config-policy-tag)# end
```

The policy tag is created and associated with the specified WLAN and policy.

Attach the policy profile to an AP

Attach the Policy Profile to an AP using commands.

Assign a policy profile to a specific AP to enforce wireless network policies.

Use this procedure when you need to apply or change the policy profile for an AP in your wireless network using CLI commands.

Procedure

1. Enter AP configuration mode.

   Example

   ```
   Device(config)# ap ap-ether-mac
   ```

   Example

   ```
   Device(config)# ap 9412.1212.1201
   ```

2. Specify the policy tag that is to be attached to the AP.

   Example

   ```
   Device(config-ap-tag)# policy-tag policy-tag
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config-ap-tag)# end
   ```

The AP is now configured with the specified policy profile.

Verify APM

Verify Application Performance Monitoring.

Use the following commands to verify application performance monitoring configuration.

To check application performance monitoring statistics, use these commands:

```
Device# show flow exporter statistics

Flow Exporter apm_exp:
  Packet send statistics (last cleared 4w1d ago):
    Successfully sent:         2082                  (216624 bytes)
!Packet sent count sent from controller to Cisco Cisco Catalyst Center
    Reason not given:          1099                  (114296 bytes)

  Client send statistics:
    Client: Flow Monitor avc
      Records added:           0
      Bytes added:             0
```

```
Device# show flow monitor assurance cache
```

```
Cache type:                                 Normal (Platform cache)
  Cache size:                                 200000
  Current entries:                                 0
  High Watermark:                                  1
!Controller flow monitor cache statistics

  Flows added:                                     6
  Flows aged:                                      6
    - Active timeout      (    10 secs)          6
```

To check status of application performance monitoring, use these command

```
Device# show avc status

VAP FNF-STATUS AVC-QOS-STATUS SD AVC-STATUS APM-STATUS
!APM-STATUS contains IPv4, IPv6 assurance and assurance-rtp monitors.

0   Disabled   Disabled       Enabled       IPV4,IPV4-RTP,IPV6,IPV6-RTP
1   Disabled   Disabled       Disabled      Disabled
2   Disabled   Disabled       Disabled      Disabled
3   Disabled   Disabled       Disabled      Disabled
4   Disabled   Disabled       Disabled      Disabled
5   Disabled   Disabled       Disabled      Disabled
6   Disabled   Disabled       Disabled      Disabled
7   Disabled   Disabled       Disabled      Disabled
8   Disabled   Disabled       Disabled      Disabled
9   Disabled   Disabled       Disabled      Disabled
10  Disabled   Disabled       Disabled      Disabled
11  Disabled   Disabled       Disabled      Disabled
12  Disabled   Disabled       Disabled      Disabled
13  Disabled   Disabled       Disabled      Disabled
14  Disabled   Disabled       Disabled      Disabled
15  Disabled   Disabled       Disabled      Disabled
```

107 Wireless Clients Threshold Warning

Topics:

- Wireless client threshold warnings

Describes how to configure periodic warnings and threshold percentages so the controller issues syslog, SNMP, and NETCONF/YANG notifications when connected wireless clients approach capacity, enabling proactive capacity management.

Wireless client threshold warnings

This concept explains how wireless client threshold warnings in Cisco IOS XE 17.6.x help administrators manage client limits by sending notifications when the number of wireless clients on a controller approaches a threshold that you define.

A wireless client threshold warning is a controller feature that

- lets you configure warning messages when the number of simultaneous wireless clients reaches a set threshold,
- sets the threshold by default to seventy-five percent of the controller's total capacity,
- notifies users through syslog messages, Simple Network Management Protocol (SNMP) traps, and NETCONF or YANG notifications when the threshold is breached.

Additional information

In Cisco IOS XE 17.6.x, this feature is enabled by default. For example, the Cisco Catalyst 9800-80 Wireless Controller supports up to 64,000 (sixty-four thousand) clients. The default threshold is 48,000 (forty-eight thousand) clients (seventy-five percent of capacity).

When the number of clients exceeds the threshold, the controller sends notifications using syslog messages, Simple Network Management Protocol (SNMP) traps, and NETCONF or YANG notifications.

This feature notifies you when you approach the wireless client limit, so you can act before reaching the maximum. You can also change the allowed number of wireless clients as needed.

> **Note**
>
> To disable the wireless client threshold warning feature, use the **no wireless max-warning** command.

Configure a warning period (CLI)

Learn how to configure a warning period for wireless client checks using CLI commands.

Set the time interval for generating wireless client warning notifications on devices using the CLI

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the periodicity of the wireless client check.

   Example

   ```
   Device(config)# wireless max-warning period interval-in-mins
   ```

   Valid values range from 1 to 60 minutes.

3. Return to privileged EXEC mode.

Example

```
Device(config)# end
```

The device generates wireless client warnings at the configured interval.

Configure the client threshold (CLI)

Learn how to configure the client threshold using CLI commands to set a warning threshold for the maximum number of wireless clients.

Set a threshold percentage to receive warnings when the number of connected wireless clients approaches the maximum limit.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure the warning threshold percentage for the maximum number of wireless clients. Valid values range from 50 to 100 percent.

   Example

   ```
   Device(config)# wireless max-warning threshold clients threshold_percentage
   ```

3. Return to privileged EXEC mode.

   Example

   ```
   Device(config)# end
   ```

The device issues a warning when the number of connected wireless clients exceeds the specified threshold percentage of the maximum limit.

108 Intelligent Capture Hardening

Topics:

- Cisco Intelligent Capture (iCAP) feature and enhancements

This chapter explains configuring and verifying anomaly detection and RF statistics for Cisco APs, showing CLI commands for AP profiles and individual APs so administrators can detect, aggregate, and troubleshoot wireless client and AP issues.

Cisco Intelligent Capture (iCAP) feature and enhancements

Use Cisco Intelligent Capture Hardening to improve troubleshooting for wireless clients and APs by aggregating data and providing features such as anomaly detection and RF statistics.

The Cisco Intelligent Capture (iCAP) feature is a troubleshooting tool for wireless clients and APs that provides aggregated data and enhanced analysis capabilities.

- The feature aggregates data from wireless controllers and APs to make troubleshooting easier,
- the feature includes enhancements such as anomaly detection and RF statistics,
- the feature facilitates the identification of onboarding and transmission issues for wireless clients.

Feature history for Cisco Intelligent Capture hardening

This table provides release and related information about the feature explained in this section.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 105: Feature history

Release	Feature	Feature information
Cisco IOS XE Dublin 17.12.1	Cisco Intelligent Capture (iCAP) Hardening	The following enhancements are made to the iCAP feature: • Anomaly Detection • RF Statistics

Additional information

Use the Cisco Intelligent Capture (iCAP) feature in the Cisco DNA Center GUI to identify the cause of onboarding or AP transmission issues by gathering and displaying data from wireless controllers and APs.

For example, you can use the iCAP feature's anomaly detection and RF statistics to quickly identify and resolve wireless client onboarding issues.

Note

In Cisco IOS XE 17.15.2, iCAP virtual interface processor (VIP) packet capture is supported only for 802.11ax clients. iCAP VIP or full packet capture is not supported for 802.11be clients.

Anomaly detection

This topic explains the concept of Anomaly Detection in Cisco APs, describing its purpose, how it works, and its importance in identifying and preventing network issues.

An anomaly is a network event type that

- allows Cisco APs to detect possible irregularities in the behavior or lifecycle of wireless clients and APs

- informs the network administrator of issues, enabling identification of what happened and how to avoid recurrence, and
- supports aggregation and suppression of repeated anomaly notifications to prevent overwhelming Cisco DNA Center with duplicate events from the same client or event type.

How anomaly detection works

Anomaly detection is crucial in identifying network problems and understanding their root causes. Whenever Cisco APs detect an anomaly, they send individual anomaly events to Cisco Catalyst Center. To avoid flooding Cisco Catalyst Center with repeated events of the same type or from the same client within a short time frame, system enhancements automatically collapse and aggregate repeats into a single event.

Anomaly detection configuration enhancements are available on the controller, which now provisions and displays the iCAP (Intelligent Capture) status, providing better visibility into anomaly detection and troubleshooting.

Example of anomaly detection

If a wireless client repeatedly triggers the same anomaly, the AP aggregates these into a single event before sending it to Cisco Catalyst Center, allowing administrators to act on consolidated insights without being overwhelmed by redundant notifications.

RF statistics

This topic explains RF statistics, which provide information about the radio frequency (RF) environment and performance of connected access points (APs) in a wireless network.

A set of RF statistics is a data collection feature that

- gathers real-time and historical information about the radio frequency environment,
- measures the performance and health indicators of wireless network access points, and
- supports monitoring and troubleshooting by providing details such as signal quality, noise levels, and channel usage.

Additional information

In Cisco IOS XE 17.12.1 and later, per-AP RF statistics are delivered directly from the wireless controller through iCAP subscription. In earlier versions (up to Cisco IOS XE 17.11.1), only basic statistical information was available.

Configure anomaly detection in AP profile (CLI)

Learn how to configure anomaly detection in an AP profile using CLI commands to enable and customize client anomaly-detection reporting.

Enable individual anomaly detection and detailed reporting for clients in an AP profile.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# onfigure terminal
   ```

2. Configure an AP profile and enter AP profile configuration mode.

Example

```
Device(config)# ap profile ap-profile
```

3. Enable individual reports for client anomaly-detection subscription.

   Example

   ```
   Device(config-ap-profile)# icap subscription client anomaly-detection
   report-individual enable
   ```

4. Enable individual reports aggregation for client anomaly-detection subscription.

   Example

   ```
   Device(config-ap-profile)# icap subscription client anomaly-detection
   report-individual enable aggregate
   ```

   This command is disabled by default.

5. Configure event reports per client, every five minutes.

   Example

   ```
   Device(config-ap-profile)# icap subscription client anomaly-detection
   report-individual per-client throttle number-of-event-reports
   ```

   The value of an event report ranges from 0 to 50 reports. The default value is five reports.

6. Configure event reports per type, every five minutes.

   Example

   ```
   Device(config-ap-profile)# icap subscription client anomaly-detection
   report-individual per-type throttle number-of-event-reports
   ```

   The value of an event report ranges from 0 to 100 reports. The default value is five reports.

Anomaly detection is activated for the AP profile, and the system generates individual and aggregated anomaly reports.

Configure anomaly detection in an AP (CLI)

Learn how to configure anomaly detection in an Access Point using CLI commands.

Enable and configure anomaly detection features on a specific access point using CLI commands.

Procedure

1. Enter privileged EXEC mode.

   Example

   ```
   Device> enable
   ```

2. Enable individual reports for client anomaly-detection subscription for a single AP.

   Example

   ```
   Device# ap name ap-name icap subscription client anomaly-detection
   report-individual enable
   ```

3. Enable individual reports aggregation for client anomaly-detection subscription, for a single AP.

   Example

   ```
   Device# ap name ap-name icap subscription client anomaly-detection
   report-individual enable
   ```

4. Configure event reports per client, every five minutes, for a single AP.

   Example

   ```
   Device# ap name ap-name icap subscription client anomaly-detection
   report-individual per-client throttle number-of-event-reports
   ```

   The value of an event report ranges from 0 to 50 reports.

5. Configure event reports per type, every five minutes, for a single AP.

   Example

   ```
   Device# ap name ap-name icap subscription client anomaly-detection
   report-individual per-type throttle number-of-event-reports
   ```

   The value of an event report ranges from 0 to 100 reports.

Anomaly detection is enabled on the targeted AP, and report generation is configured according to your specified parameters.

Verify anomaly detection and RF statistics

Verify Anomaly Detection and RF Statistics.

To verify the current status of the anomaly-detection subscription of an AP, use this command:

```
Device# show ap name cisco-AP icap subscription client anomaly-detection chassis
 active R0
Per-AP ICap configuration

Anomaly detection subscription
  State                     : enabled
  Client filter             : 006b.f107.a520
  Client filter             : 006b.f107.a521
  DHCP timeout (seconds)    : 5
  Trigger AP packet trace   : enabled
  Report Individual         : enabled
  Report Individual aggregate : enabled
  Report Individual throttled events (per 5 minute) : 5
  Report Individual per type throttled events (per 5 minute) : 14
  Report Individual per client throttled events (per 5 minute) : 15
```

```
  Report Summary           : disabled
  Report Summary frequency (minutes) : 5
```

To verify RF statistics, use this command:

> **Note**
>
> The controller **show** command is enhanced to display data from the **txTotalDrops** counter.

```
Device# show wireless client mac-address 00XX.ecXX.7aXX detail
.
.
.
Client Statistics:
  Number of Bytes Received from Client : 62861
  Number of Bytes Sent to Client : 6754
  Number of Packets Received from Client : 455
  Number of Packets Sent to Client : 65
  Number of Data Retries : 0
  Number of RTS Retries : 0
  Number of Tx Total Dropped Packets: x
  Number of Duplicate Received Packets : 0
  Number of Decrypt Failed Packets : 0
  Number of Mic Failured Packets : 0
  Number of Mic Missing Packets : 0
  Number of Policy Errors : 0
  Radio Signal Strength Indicator : -21 dBm
  Signal to Noise Ratio : 73 dB
.

.
```

109 Amazon S3 Support

Topics:

- Amazon S3 support

This chapter explains how to configure and verify Amazon S3 cloud storage on Cisco Catalyst devices, including creating S3 profiles, setting credentials, permissions, region and mount points, and commands to enable and confirm operational status.

Amazon S3 support

Amazon Simple Storage Service (Amazon S3) support lets you use scalable, cloud-based storage from Amazon Web Services (AWS) with your Cisco Catalyst device. You can supplement onboard storage for software images, logs, and maintenance updates.

Cisco Catalyst devices support Amazon Simple Storage Service (Amazon S3), a cloud storage solution from Amazon Web Services (AWS). With this integration, you can expand built-in persistent storage to meet increased demands for file storage, logging, and software management.

- You get flexible, scalable storage for large software images and higher logging rates.
- You can distribute software images, service maintenance updates (SMUs), and scripts across multiple devices.
- You can enhance device capabilities by adding cloud storage to existing onboard resources.

Amazon S3 support overview and details

As software images grow and logging requirements increase, you may need additional storage capacity on your Cisco Catalyst device.

Built-in persistent storage may not be sufficient. Starting with IOS-XE release 17.13.1, Cisco Catalyst 9800 Series Wireless Controllers support Amazon Simple Storage Service (Amazon S3).

Amazon S3 is a scalable cloud storage infrastructure that you can access through a web interface.

With Amazon S3 support, you can supplement onboard storage to meet new operational and maintenance demands.

Restrictions and guidelines

This section describes the restrictions and guidelines for configuring and accessing cloud storage.

These restrictions and guidelines apply to cloud storage configuration:

- Only the active device can access the cloud storage.
- You can establish cloud reachability through any service port, including device management ports or forwarding interfaces on the device.
- You can create multiple cloud storage configuration profiles for the same Amazon Simple Storage Service (S3) bucket using different configuration parameters.
- If you host virtual device instances (such as C9800-CL) on AWS, you can use the Identity and Access Management (IAM) role infrastructure to access Amazon Simple Storage Service (S3) storage.

Configure Amazon S3 support (CLI)

Learn how to configure Amazon S3 support by using CLI commands to enable cloud storage integration on your device.

Configure Amazon S3 support so your device can use Amazon S3 cloud storage for remote data management and backup.

Before you begin

- Ensure that connectivity to the cloud is established.
- Ensure that you have the AWS Identity and Access Management (IAM) access key ID and secret key ID.
- Ensure that DNS is configured. If DNS is not configured, S3 bucket resolution fails.

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an Amazon S3 cloud services profile.

   Example

   ```
   Device(config)# cloud-services aws s3 profile profile-name
   ```

   Use only alphanumeric characters for the profile name. The underscore (_) is the only supported special character.

3. Configure the Amazon S3 storage bucket and its mount point.

   Example

   ```
   Device(config-s3fs-profile)# bucket bucket-name mount-point s3-mount
   ```

   A bucket is a container for objects stored in Amazon S3.

   The mount point is the directory on your local file system where you mount the Amazon S3 bucket.

   > **Note**
   >
   > Ensure that DNS is configured.

4. Optional: Add a description to the Amazon S3 cloud services profile.

   Example

   ```
   Device(config-s3fs-profile)# description profile-description
   ```

   You can enter a description of up to 255 alphanumeric characters.

5. Optional: Configure the management interface to serve as the VRF interface.

   Example

   ```
   Device(config-s3fs-profile)# vrf mgmt-Intf
   ```

   By default, the forwarding interface is used.

6. Configure the AWS S3 access credentials.

   Example

   ```
   Device(config-s3fs-profile)# access-key key-id iam-id secret-key { 0 | 8 }
   secret-key
   ```

Use the access key ID and secret key that were created for the IAM role in the AWS Management Console.

7. Set the Amazon S3 bucket to read and write permissions.

   Example

   ```
   Device(config-s3fs-profile)# permissions read-write
   ```

   By default, read-only permission is enabled.

8. Specify the Amazon S3 region where the cloud-based storage is used.

   Example

   ```
   Device(config-s3fs-profile)# region region
   ```

9. Configure the HTTP server URL, the HTTPS server URL, or the IPv4 address, along with the port details.

   Example

   ```
   Device(config-s3fs-profile)# proxy https-server url-ip port port-num
   ```

10. Save the configuration and enable it for Amazon S3 services.

    Example

    ```
    Device(config-s3fs-profile)# no shutdown
    ```

11. Return to global configuration mode.

    Example

    ```
    Device(config-s3fs-profile)# exit
    ```

After completing these steps, you can securely access Amazon S3 storage buckets and manage cloud storage operations through the CLI.

Verify Amazon S3 support

Verifying Amazon S3 Support.

To view a summary of all the Amazon S3 profiles, use this command.

```
Device# show cloud-services aws s3 summary

Profile Name                        Profile Status  Service Status
-------------------------------------------------------------------
test                                Started         Active

test2                               Started         Active
```

To view the operational information of a Amazon S3 profile, use this command.

```
Device# show cloud-services aws s3 profile s1

Profile Details

Profile Name          : s1
Bucket Name           : pb-s3-test1
Mount Point           : test
Bucket Permission     : Read-Only
Region                : us-west-1
VRF                   : Global

S3 Service Details

Service Status        : Active
Service PID           : 31934
Mount Time            : 09/28/23 17:06:25
Service Log Level     : Notice
```

110 Amazon Web Services CloudWatch

Topics:

- Amazon Web Services CloudWatch Support

This chapter explains how to configure and verify integration with AWS monitoring services on supported Cisco controllers, detailing prerequisites, CLI profile and credential setup, log group/stream selection, and secure syslog streaming.

Amazon Web Services CloudWatch Support

This concept explains the monitoring and observability features provided by Amazon Web Services (AWS) CloudWatch, including integration with Amazon Elastic Compute Cloud (EC2) instances and on-premises controllers to collect, transmit, and analyze system logs, metrics, and events.

A CloudWatch feature is a monitoring capability that

- collects and aggregates system logs, metrics, and events from Amazon Elastic Compute Cloud (EC2) instances and on-premises controllers,
- transmits these data points to the AWS CloudWatch server for centralized monitoring, and
- provides insights into the performance, health, and operation of applications and resources running on AWS infrastructure.

Additional Information

AWS CloudWatch is a service in the Amazon Web Services (AWS) cloud platform. It monitors server system logs, metrics, and events.

Organizations can integrate CloudWatch with Amazon Elastic Compute Cloud (EC2) instances and on-premises servers. This integration enables efficient transmission of logs, events, and metrics to the AWS CloudWatch server.

The CloudWatch service enables detailed insights into applications, resources, and services running on AWS infrastructure. These insights help ensure performance, support troubleshooting, and maintain the overall health of controllers and systems.

The CloudWatch service is disabled by default and must be enabled to function.

When the AWS CloudWatch agent is active on a controller, the agent gathers system logs from the controller and transmits them securely to the AWS CloudWatch server.

Example: Using AWS CloudWatch for Monitoring

The AWS CloudWatch agent can be used to:

- collect internal system-level metrics from Amazon Elastic Compute Cloud (EC2) instances across multiple operating systems, and
- collect system-level metrics from on-premises devices or controllers.

Benefits of Amazon web services CloudWatch service

This topic explains Amazon Web Services (AWS) CloudWatch features, including unified monitoring, enhanced operational efficiency, and actionable insights through analytics and visualizations.

The AWS CloudWatch feature provides unified monitoring, operational efficiency, and actionable insights for cloud environments.

- **A unified monitoring and observability platform** : All device logs are consolidated in a single location, facilitating easy event monitoring and seamless action using the cloud services tools.
- **Enhanced operational efficiency and resource optimization** : Automate the processes and establish alarms for specific events or logs, thereby improving operational performance and resource management.
- **Gain valuable insights from logs** : Analyze and visualize the logs, allowing you to take appropriate actions based on the events and logs.

The AWS CloudWatch feature is supported on the following controllers: Cisco Catalyst 9800-40, 9800-80, 9800-L, and 9800-CL (private [VMware ESXI, KVM, Hyper-V] and public cloud [AWS C9800-CL instances only] platforms).

Configure an AWS CloudWatch Profile (CLI)

Configure an Amazon Web Services (AWS) CloudWatch profile using CLI commands to stream syslog messages and enable centralized monitoring.

Configure an AWS CloudWatch profile using CLI commands. This configuration enables secure streaming of syslog messages and log data to AWS CloudWatch for centralized logging and monitoring.

The AWS CloudWatch agent transmits buffered syslog messages to the AWS CloudWatch service.

The agent scans and retrieves logs from files in a designated directory. You can specify a single file or use a wildcard pattern to include multiple files.

You can specify the storage location in the AWS CloudWatch agent profile. When files are updated, the agent reads their content.

Before you begin

- Create CloudWatch groups and streams in AWS.
- Create access credentials in AWS.
- Set a Private Configuration Key for Password Encryption
- Ensure that you have the AWS Identity and Access Management (IAM) access key ID and secret key.
- You can run the optional **logging buffered** and **logging persistent** commands to send syslogs to AWS CloudWatch.
- Ensure that DNS is configured.

To create CloudWatch groups and streams, see the AWS documentation: https://docs.aws.amazon.com/IAM/latest/UserGuide/introduction.html

Procedure

1. Enter global configuration mode.

   Example

   ```
   Device# configure terminal
   ```

2. Configure an AWS CloudWatch profile.

   Example

   ```
   Device(config)# cloud-services aws cloudwatch profile profile-name
   ```

3. Optional: Add a description to the AWS CloudWatch profile.

   Example

   ```
   Device(config-cloudwatch-profile)# description profile-description
   ```

4. Optional: Configure the HTTP or HTTPS server URL or IP address and port.

Example

```
Device(config-cloudwatch-profile)# proxy https-server url-ip port port-num
```

5. Optional: Configure the management interface as the VRF interface.

   Example

   ```
   Device(config-cloudwatch-profile)# vrf mgmt-Intf
   ```

   Use this option to send agent traffic through the management interface. By default, the data port interface is used.

   Use this command only if the management interface is available. This interface is not available in C9800-CL public cloud instances.

6. Configure the AWS CloudWatch access credentials.

   Example

   ```
   Device(config-cloudwatch-profile)# access-key key-id iam-key-id secret-key 0
    secret-key
   ```

   Use the access key ID and secret key created for the IAM user in the AWS console.

7. Specify the AWS region where the CloudWatch server is running.

   Example

   ```
   Device(config-cloudwatch-profile)# region us-west-1
   ```

8. Specify the AWS CloudWatch log group name, log stream name, and optionally the log file path.

   Example

   ```
   Device(config-cloudwatch-profile)# log group-name group-name stream-name
   stream-name file-path file-path
   ```

   If you do not provide a log file path, the system uses the default syslog path: /bootflash/syslog/

   The log group and log stream must match those created in AWS CloudWatch.

   If specified, the log file path does not need to match the buffered logging persistent storage directory or file name.

9. Save and enable the configuration for AWS CloudWatch services.

   Example

   ```
   Device(config-cloudwatch-profile)# no shutdown
   ```

10. Return to global configuration mode.

    Example

    ```
    Device(config-cloudwatch-profile)# exit
    ```

The AWS CloudWatch profile is configured and enabled. The device can now transmit syslog messages and log data to the specified AWS CloudWatch log group and stream for monitoring and integration with AWS services.

Verify AWS CloudWatch configuration

Verify AWS CloudWatch Configuration.

To view summary of AWS CloudWatch profiles, run this command:

```
Device# show cloud-services aws cloudwatch summary

Profile Name                      Profile Status  Service Status
-------------------------------------------------------------------
demo3                             Started         Active

demo4                             Started         Active
```

To view details of a specific AWS CloudWatch profile, run this command:

```
Device# show cloud-services aws cloudwatch profile demo3

Profile Details

Profile Name          : demo3

111 Kernel Minidump and Trustzone Upgrade

Topics:

- Kernel minidump and trust zone upgrade

This chapter describes how to enable and configure kernel minidump collection and automatic TrustZone upgrades on supported Cisco APs, guiding administrators through setup, limits, verification, and retrieving crash TLV files for analysis.

Kernel minidump and trust zone upgrade

This topic explains the Kernel Minidump and Trustzone Upgrade feature, which provides methods for diagnosing kernel crashes on Wi-Fi 6 (802.11AX) access points (APs) by collecting and exporting critical crash data.

The kernel minidump and trust zone upgrade feature is a diagnostic capability that

- collects and preserves kernel and driver data structures when a crash occurs
- stores these data structures for post-crash analysis in a standardized Type-Length-Value (TLV) format
- automatically upgrades the trust zone on supported devices so the system can collect CPU registers for comprehensive debugging.

Feature History for kernel minidump and trustzone upgrade support

This table provides release and related information for the feature explained in this module.

This feature is also available in all the releases subsequent to the one in which they are introduced in, unless noted otherwise.

Table 106: Feature history

Release	Feature information
Cisco IOS XE 17.18.1	This feature enhances control over minidump collection on Wi-Fi 7 (802.11be) APs. A new option has been added to limit the number of kernel core dump directories stored on the AP. This command has been modified: • **core-dump kernel dir-limit** Support has been added for these access points: • Cisco Wireless 9178 Series Access Points. • Cisco Wireless 9176 Series Access Points.
Cisco IOS XE 17.14.1	Kernel Minidump and Trustzone Upgrade feature offers a more effective method for diagnosing kernel issues. This command is introduced: • **core-dump kernel type**

Feature overview

Traditionally, when a kernel crash occurs on Wi-Fi 6 (802.11AX) access points, only AP console logs are available for troubleshooting. However, these logs often lack the detail needed to determine the root cause accurately.

The kernel minidump and trust zone upgrade feature, introduced in Cisco IOS XE 17.14.1, provides a more effective method for diagnosing kernel crashes. The feature captures and organizes internal data structures critical for debugging so you can troubleshoot problems more accurately.

How kernel minidumps work

When you enable the feature, the system collects references to key kernel or driver structures. It stores them in a Type-Length-Value (TLV) format in kernel memory.

After a crash and the access point reboots, the system writes the referenced data structures to the */storage/cores* directory on the access point flash memory. You can export these files for advanced analysis.

Trust zone upgrade

In AP using Qualcomm Software Development Kit (QSDK) version 11.3, the trust zone module collects CPU registers after a crash. It then preserves these registers for later retrieval by the crash dump process.

When you enable the kernel minidump and trust zone upgrade feature, the system automatically upgrades the trust zone to the latest version on supported access points.

> **Note**
>
> The trust zone upgrade occurs only once. If you disable the Kernel Minidump and Trustzone Upgrade feature or downgrade the controller software to a release earlier than Cisco IOS XE 17.14.1, the trust zone upgrade does not roll back.

Supported APs

You can use the kernel minidump and trust zone upgrade feature on the following access points running Cisco IOS XE 17.14.1 or later:

- Cisco Catalyst 9124 Series Access Points
- Cisco Catalyst 9136 Series Access Points

Example: Kernel minidump and trust zone upgrade in action

After you enable the feature, if a supported access point experiences a kernel crash, you can access the TLV files in the */storage/cores* directory and export them. This provides comprehensive diagnostic data to accelerate root cause analysis and issue resolution.

Configure the Minidump from the AP (CLI)

Learn how to configure minidump collection on an access point (AP) using the command-line interface (CLI). Use this procedure to enable kernel coredump collection directly from the AP.
